Language Environment Programming Guide
Sixth Edition, September 2004
This is a major revision of SA22-7561-04.
This edition applies to Language Environment in z/OS Version 1, Release 6 (5694-A01), to z/OS.e™ Version 1, Release 6(5655-G52), and to all subsequent releases and modifications until otherwise indicated in new editions.

IBM welcomes your comments. A form for readers’ comments may be provided at the back of this document, or you may address your comments to the following address:

International Business Machines Corporation
Department 55JA, Mail Station P384
2455 South Road
Poughkeepsie, NY 12601-5400
United States of America

FAX (United States & Canada): 1+845+432-9405
FAX (Other Countries):
  Your International Access Code +1+845+432-9405

IBMLink™ (United States customers only): IBMUSM10(MHVRCFS)
Internet e-mail: mhvrcfs@us.ibm.com

If you would like a reply, be sure to include your name, address, telephone number, or FAX number.

Make sure to include the following in your comment or note:
• Title and order number of this document
• Page number or topic related to your comment

Summary of changes  ................................................... xxix

Part 1. Creating Applications with Language Environment.  .... 1

Chapter 1. Introduction to Language Environment ................. 3
Components of Language Environment  ............................. 3
Common Run-Time Environment of Language Environment ....... 4

Chapter 2. Preparing to Link-Edit and Run under Language Environment 7
Understanding the Basics  ........................................... 7
   Planning to Link-Edit and Run.  ............................... 8
   Link-Editing Single-Language Applications ................ 9
   Link-Editing ILC Applications  ................................. 10
Downward Compatibility Considerations.  ........................ 10
Checking Which Run-Time Options Are in Effect .................. 13
HLL Compatibility Considerations  ............................... 13
C/C++ AMODE/RMODE Considerations.  ........................ 14
COBOL Considerations.  ............................................ 14
   Replacing COBOL Library Routines in a COBOL Load Module 14
   Using Language Environment Resident Routines for Callable Services 14
Fortran Considerations.  ............................................ 15
   Replacing Fortran Run-Time Library Modules in a Fortran Executable Program 15
   Using the Fortran Library Module Replacement Tool .......... 16
   Resolving Static Common Block Name Conflicts .............. 16
   Resolving Library Module Name Conflicts between Fortran and C 17
PL/I Considerations  .................................................. 24
   Link-editing PL/I Subroutines for Later Use ................. 24
   Replacing PL/I Library Routines in an OS PL/I Executable Program 25
   Link-Editing Fetchable Executable Programs ............... 25
PL/I Link-Time Considerations  .................................... 26
   Fetching Modules with Different AMODEs ................. 26

Chapter 3. Using Extra Performance Linkage (XPLINK) ........... 29
What is XPLINK?  ..................................................... 29
Objectives  ........................................................... 29

© Copyright IBM Corp. 1995, 2004
107

Accepting the default run-time options .................................................. 83
OVERRIDING THE DEFAULT RUN-TIME OPTIONS ....................................... 83
Link-editing and running ............................................................................. 84
Link-editing your application using the LINK command ............................... 84
Using CMOD CLIST to invoke the TSO/E LINK command ........................ 85
Using the CALL command to run your application ........................................ 87
TSO/E parameter list format ...................................................................... 88
Loading and running using the LOADGO command .................................... 88
Allocating data sets under TSO/E ............................................................... 89
Example of using LOADGO .......................................................................... 89
Link-edit and loader options ....................................................................... 89
Using the iconv utility and ICONV CLIST for C/C++ .............................. 90
Using the genxlt utility and GENXLT CLIST for C/C++ .............................. 91
Running your application under TSO/E ........................................................ 91

Chapter 7. Creating and Executing Programs using z/OS UNIX System Services ................................................................. 93
Basic Link-Editing and Running C/C++ Applications under z/OS UNIX ...... 93
Invoking a Shell from TSO/E ...................................................................... 94
Using the z/OS UNIX c89 Utility to Link-Edit and Create Executable Files .... 94
Running z/OS UNIX C/C++ Application Programs ...................................... 94
z/OS UNIX Application Program Environments .......................................... 95
Placing an MVS Application Executable Program in the File System ........ 95
Restriction on Using 24-Bit AMODE Programs ........................................... 95
Running an MVS Executable Program from a z/OS UNIX Shell ............... 95
Running POSIX-enabled Programs .............................................................. 96
Running COBOL Programs under z/OS UNIX .......................................... 98
Basic Link-Editing and Running PL/I Routines under z/OS UNIX with POSIX(ON) ....................................................... 99
Basic Link-Editing and Running PL/I MTF Applications under z/OS UNIX 100

Chapter 8. Using IBM-Supplied Cataloged Procedures ................................ 103
Invoking Cataloged Procedures ................................................................ 103
Step Names in Cataloged Procedures ......................................................... 103
Unit Names in Cataloged Procedures ......................................................... 104
Data Set Names in Cataloged Procedures .................................................. 104
IBM-Supplied Cataloged Procedures .......................................................... 105
CEEWG — Load and Run a Language Environment-Conforming Non-XPLINK Program ....................................................... 107
CEEWL — Link a Language Environment-Conforming Non-XPLINK Program 108
CEEWLGI — Link and Run a Language Environment-Conforming Non-XPLINK Program ...................................................... 109
CEEEXR — Load and Run a Language Environment-Conforming XPLINK Program .............................................................. 109
CEEEXL — Link-Edit a Language Environment-Conforming XPLINK Program ............................................................. 110
CEEEXLR — Link and Run a Language Environment-Conforming XPLINK Program ............................................................. 111
AFHWL — Link a Program Written in Fortran .......................................... 111
AFHWLGI — Link and Run a Program Written in Fortran ......................... 112
AFHWN — Resolving Name Conflicts between C and Fortran ................. 113
Modifying Cataloged Procedures ............................................................... 114
OVERRIDING AND ADDING TO EXEC Statements .............................. 114
OVERRIDING AND ADDING DD Statements ........................................... 114
OVERRIDING GENERIC LINK-EDIT Procedures for Constructed Reentrant Programs ......................................................... 115

Contents  V
Part 2. Preparing an Application to Run with Language Environment

Chapter 10. Using Language Environment Parameter List Formats
Understanding the Basics ............................. 131
Argument Lists and Parameter Lists .................. 132
Passing Arguments between Routines ................ 132
Preparing Your Main Routine to Receive Parameters 134
   PL/I Argument Passing Considerations .......... 138

Chapter 11. Making Your Application Reentrant
Understanding the Basics ............................. 139
Making Your C/C++ Program Reentrant ................ 139
   Natural Reentrancy ............................... 139
   Constructed Reentrancy ......................... 139
   Generating a Reentrant Program Executable for C or C++ 140
Making Your COBOL Program Reentrant ............... 140
Making Your Fortran Program Reentrant ............... 140
Making Your PL/I Program Reentrant .................. 141
Installing a Reentrant Load Module ................... 141

Part 3. Language Environment Concepts, Services, and Models

Chapter 12. Initialization and termination under Language Environment 145
Understanding the basics ............................. 145
Language Environment Initialization ................ 146
   What Happens During Initialization .......... 147
Language Environment Termination .................. 148
   What causes termination ...................... 148
   What happens during termination .......... 149
Managing return codes in Language Environment .... 151
   How the Language Environment enclave return code is calculated 151
   Setting and altering user return codes ........ 152
Termination behavior for unhandled conditions ...... 154
   Determining the abend code ................... 155

Chapter 13. Program Management Model ................ 159
Understanding the Basics ............................. 159
Language Environment Program Management Model Terminology 159
Processes ........................................... 161
Enclaves ............................................ 162
Threads ............................................. 163
Chapter 17. Coding a user-written condition handler

Understanding the basics

PL/I Considerations

Types of conditions you can handle

User-written condition handler interface

Registering user-written condition handlers using USRHDLR

Nested conditions

Using Language Environment condition handling with nested COBOL programs

Examples with a registered user-written condition handler

Handling a divide-by-zero condition in C, C++, COBOL, or PL/I

Handling an out-of-storage condition in C, C++, COBOL, or PL/I

Signaling and handling a condition in a C/C++ routine

Handling a divide-by-zero condition in a COBOL program

Handling a program check in an assembler routine

Chapter 18. Using Condition Tokens

Understanding the Basics

The Effect of Coding the fc Parameter

Testing a Condition Token for Success

Testing Condition Tokens for Equivalence

Testing Condition Tokens for Equality

Effects of Omitting the fc Parameter

Understanding the Structure of the Condition Token

Using Symbolic Feedback Codes

Locating Symbolic Feedback Codes for Conditions

Including Symbolic Feedback Code Files

Examples Using Symbolic Feedback Codes

Condition Tokens for C Signals under C and C++

q_data Structure for Abends

Usage Notes

Example Illustrating Retrieval of q_data

q_data Structure for Arithmetic Program Interruptions

Usage Notes

q_data Structure for Square-Root Exception
q_data Structure for Math and Bit-Manipulation Conditions .................. 304
Usage Notes ......................................................... 308
Format of q_data Descriptors ........................................... 308

Chapter 19. Using and Handling Messages ........................................... 311
Understanding the Basics .................................................. 311
Creating Messages ...................................................... 311
Creating a Message Source File .......................................... 312
Using the CEEBLDTX Utility ............................................. 315
Files Created by CEEBLDTX ............................................. 315
Creating a Message Module Table ........................................ 318
Assigning Values to Message Inserts .................................... 319
Interpreting Run-Time Messages ......................................... 320
Specifying National Language ............................................. 322
Run-Time Messages with POSIX ......................................... 322
Handling Message Output ................................................ 323
Using Language Environment MSGFILE .................................. 324
Using MSGFILE under z/OS UNIX ....................................... 324
Using C or C++ I/O Functions ........................................... 325
Using COBOL I/O Statements ............................................ 327
Using Fortran I/O Statements ............................................ 327
Using PL/I I/O Statements ............................................... 329
MSGFILE Considerations When Using PL/I ............................. 329
Examples Using Multiple Message Handling Callable Services ......... 330
C/C++ Example Calls to CEEMOUT, CEENCOD, CEEMGET, CEEDCOD, and CEEMSG ................................. 331
COBOL Example Calls to CEEMOUT, CEENCOD, CEEMGET, CEEDCOD, and CEEMSG ........................................ 333
PL/I Example Calls to CEEMOUT, CEENCOD, CEEMGET, CEEDCOD, and CEEMSG ........................................ 336

Chapter 20. Using Date and Time Services .......................................... 339
Understanding the Basics ................................................ 339
Working with Date and Time Services .................................... 340
Date Limits .............................................................. 340
Picture Character Terms and Picture Strings ........................... 341
Notation for Eras ....................................................... 341
Performing Calculations on Date and Time Values ....................... 342
Century Window Routines ................................................. 342
National Language Support for Date and Time Services ................. 343
Examples Using Date and Time Callable Services ....................... 343
Examples Illustrating Calls to CEEQCEN and CEESCEN ............... 344
Examples Illustrating Calls to CEESCS .................................. 347
Examples Illustrating Calls to CEESCS and CEEDATM ................. 352
Examples Illustrating Calls to CEESCS, CEESCI, CEEISEC, and CEEDATM .................................................... 358
Examples Illustrating Calls to CEEAYS, CEEDATE, and CEEDYWK ........ 367
Calls to CEECBLDY in COBOL .......................................... 377

Understanding the Basics ................................................ 379
Setting the National Language .......................................... 379
Setting the Country Code ................................................. 380
Combining National Language Support and Date and Time Services .... 380
Calls to CEE3CTY, CEEFMDT, and CEEDATM in C ................... 380
Calls to CEE3CTY, CEEFMDT, and CEEDATM in COBOL .......... 382

Effect of the CICS HANDLE ABEND Command .......................... 443
Effect of the CICS HANDLE CONDITION and CICS HANDLE AID .... 443
Restrictions on User-Written Condition Handlers under CICS .... 443
CICS Transaction Abend Codes .......................................... 444
Using the CBLPSHPOP Run-Time Option under CICS ............ 444
Restrictions on Assembler User Exits under CICS ................. 444
Ensuring Transaction Rollback under CICS ......................... 445
Run-Time Output under CICS ............................................ 445
Message Handling under CICS ......................................... 445
Dump Services under CICS ............................................. 446
Support for Calls within the Same HLL under CICS .............. 446
C ................................................................. 446
C++ .............................................................. 446
COBOL .................................................................. 446
PL/I ..................................................................... 447

Chapter 26. Running Applications under DB2 ..................... 449
Understanding the Basics .................................................. 449
Language Environment Support for DB2 Applications ......... 449
Condition Handling under DB2 .......................................... 449
PL/I Consideration for DB2 Applications ............................ 449

Chapter 27. Running Applications under IMS ..................... 451
Understanding the Basics .................................................. 451
Using the Interface between Language Environment and IMS 451
z/OS C/C++ Considerations under IMS ............................. 451
C++ Considerations under IMS ...................................... 452
PL/I Considerations under IMS ...................................... 452
IMS Communication with Your Application ...................... 452
Link-Edit Considerations under IMS ............................... 453
Making Your IMS Application Reentrant ............................ 453
Condition Handling under IMS ...................................... 453
Coordinated Condition Handling under IMS ..................... 453
Diagnosing Abends with the IMS Dump ............................ 454

Part 5. Specialized Programming Tasks ................................. 455

Chapter 28. Using Run-Time User Exits ......................... 457
Understanding the Basics .................................................. 457
User Exits Supported under Language Environment .......... 457
Using the Assembler User Exit CEEBXITA ................. 458
Using the HLL Initialization Exit CEEBINT ......... 458
PL/I and C Compatibility .............................................. 459
Using Sample Assembler User Exits ............................... 459
When User Exits Are Invoked ........................................ 460
CEEBXITA Behavior During Enclave Initialization .... 461
CEEBXITA Behavior During Enclave Termination .... 461
CEEBXITA Behavior During Process Termination .......... 462
Specifying Abend Codes to Be Percolated by Language Environment 462
Actions Taken for Errors That Occur within the Exit ....... 462
CEEBXITA Assembler User Exit Interface ....................... 463
Parameter Values in the Assembler User Exit ................. 467
CEEBINT High-Level Language User Exit Interface ........... 470

Chapter 29. Assembler Considerations ......................... 475
Understanding the Basics .............................................. 475
Compatibility Considerations ................................................................. 475
Register Conventions ............................................................................. 477
Language Environment-conforming Assembler ..................................... 477
Non-Language Environment-conforming Assembler .............................. 478
Considerations for Coding or Running Assembler Routines .................... 478
Asynchronous Interrupts ......................................................................... 478
Condition Handling ................................................................................ 478
Access to the Inbound Parameter String ............................................... 479
Overlay Programs ................................................................................... 479
CEESTART, CEEMAIN, and CEEFMAIN .............................................. 479
Mode Considerations ............................................................................. 479
Language Environment Library Routine Retention (LRR) ......................... 480
Using Library Routine Retention ........................................................... 481
Library Routine Retention and Preinitialization ...................................... 481
CEEENTRY Macro — Initialize/terminate Language Environment Library 481
Routine Retention ................................................................................... 481
Assembler Macros .................................................................................. 483
CEEENTRY Macro — Generate a Language Environment-Conforming 483
Prolog ........................................................................................................ 484
CEETERM Macro — Terminate a Language Environment-Conforming 484
Routine .................................................................................................... 487
CCECAA Macro — Generate a CAA Mapping ....................................... 488
CCEEDSA Macro — Generate a DSA Mapping ....................................... 489
CCEPPA Macro — Generate a PPA ......................................................... 489
CEELOAD Macro — Dynamically Load a Language Environment- 489
Conforming Routine .............................................................................. 491
CEEFETCH Macro — Dynamically Load a Language Environment- 491
Conforming Routine .............................................................................. 494
CEERELES Macro — Dynamically Delete a Language Environment- 494
Conforming Routine .............................................................................. 498
CEEPCALL Macro — Call a Language Environment-Conforming Routine 499
CCEEDDA Macro — Define a Data Item in the Writeable Static Area (WSA) 501
CCEPLDA Macro — Returns the Address of a Data Item Defined by 501
CEEPDDA ................................................................. 503
Example of Assembler Main Routine ...................................................... 503
Example of an Assembler Main Calling an Assembler Subroutine .......... 504
Invoking Callable Services from Assembler Routines ............................. 508
System Services Available to Assembler Routines ................................ 509
Using the ATTACH Macro .................................................................... 510
Using the SVC LINK Macro ................................................................. 513

Chapter 30. Using preinitialization services .............................................. 515
Understanding the basics ....................................................................... 516
Using preinitialization ................................................................. 516
Using the PreInit table ........................................................................... 516
Reentrancy considerations .................................................................... 518
PreInit XPLINK considerations ............................................................. 519
User exit invocation ............................................................................... 520
Stop semantics ...................................................................................... 521
Preinitialization interface .................................................................... 522
Initialization ........................................................................................... 523
Application invocation ........................................................................... 529
Service routines .................................................................................... 542
An example program invocation of CEEPIPI ..................................... 549
HLLPIPI examples ................................................................................. 552
Chapter 31. Using nested enclaves ........................................ 555
Understanding the basics ............................................... 555
XPLINK considerations ................................................. 555
COBOL considerations .................................................. 556
PL/I considerations ..................................................... 556
Determining the behavior of child enclaves ................. 556
Creating child enclaves with EXEC CICS LINK or EXEC CICS XCTL 556
Creating child enclaves by calling a second main program 557
Creating child enclaves using SVC LINK .......................... 557
Creating child enclaves using the C system() function .... 560
Creating child enclaves containing a PL/I fetchable main . 561
Other nested enclave considerations ............................... 562
What the enclave returns from CEE3PRM ......................... 563
Finding the return and reason code from the enclave .... 565
Assembler user exit ..................................................... 565
Message file ............................................................ 565
COBOL multithreading considerations ......................... 565
z/OS UNIX considerations ........................................... 565
AMODE considerations ............................................... 566

Part 6. Appendixes ....................................................... 567

Appendix A. Prelinking an Application ............................. 569
Which Programs Need to Be Prelinked ......................... 569
What the Prelinker Does ............................................. 570
Prelinking Process ..................................................... 570
References to Currently Unresolved Symbols (Unresolved External
References) ........................................................... 572
Processing the Prelinker Automatic Library Call ........ 572
Language Environment Prelinker Map ............................... 573
Control Statement Processing ....................................... 577
IMPORT Control Statement ......................................... 577
INCLUDE Control Statement ......................................... 577
LIBRARY Control Statement .......................................... 578
RENAME Control Statement .......................................... 578
Mapping L-Names to S-Names ....................................... 580
Starting the Prelinker under Batch and TSO/E ............... 581
Under Batch ............................................................ 581
Under TSO/E .......................................................... 581
Using the CXXBIND EXEC under TSO/E ...................... 584
Using the CXXMOD EXEC under TSO/E ...................... 584
Prelinker Options ....................................................... 586

Appendix B. EXEC DLI and CALL IMS Interfaces .................. 589

Appendix C. Guidelines for Writing Callable Services .......... 591

Appendix D. Operating System and Subsystem Parameter List Formats 593
C and C++ Parameter Passing Considerations .................. 593
C PLIST and EXECOPS Interactions ............................... 595
C++ PLIST and EXECOPS Interactions ............................ 597
Case Sensitivity under TSO ......................................... 599
Parameter Passing Considerations with XPLINK C and C++ . 599
COBOL Parameter Passing Considerations ....................... 599
PL/I Main Procedure Parameter Passing Considerations ..... 601
### Appendix E. Object Library Utility
- Creating an Object Library ................................................. 603
  - Under Batch ........................................................................ 603
  - Under TSO ........................................................................... 604
- Object Library Utility Map .................................................... 605

### Appendix F. Using the Systems Programming Environment
- Building Freestanding Applications ........................................ 609
- Special Considerations for Reentrant Modules ......................... 611
  - Notes ................................................................................. 612
- Building System Exit Routines .............................................. 613
- Building Persistent C Environments ....................................... 613
- Building User-Server Environments ....................................... 613
- Summary ............................................................................... 613

### Appendix G. Sort and Merge Considerations
- Understanding the Basics ..................................................... 617
- Invoking DFSORT Directly .................................................. 617
- Using the COBOL SORT and MERGE Verbs ......................... 617
  - User Exit Considerations .................................................. 618
  - Condition Handling Considerations .................................. 618
- Using the PL/I PLISRTx Interface ......................................... 619
  - User Exit Considerations .................................................. 619
  - Condition Handling Considerations .................................. 620

### Appendix H. Running COBOL Programs under ISPF ................. 623

### Appendix I. Language Environment Macros ............................ 625

### Appendix J. PL/I Macros Which Activate Variables ................. 627

### Appendix K. Accessibility ................................................... 629
- Using assistive technologies ................................................ 629
- Keyboard navigation of the user interface .............................. 629
- z/OS information ............................................................... 629

### Notices .............................................................................. 631
- Programming Interface Information ..................................... 633
- Trademarks ......................................................................... 633

### Bibliography ...................................................................... 635
- Language Products Publications ......................................... 635
- Related Publications .......................................................... 636
- Softcopy Publications .......................................................... 637

### Index .................................................................................. 639

© Copyright IBM Corp. 1995, 2004
IBM z/OS Language Environment (also called Language Environment) provides common services and language-specific routines in a single run-time environment for C, C++, COBOL, Fortran (z/OS only; no support for z/OS UNIX System Services or CICS®), PL/I, and assembler applications. It offers consistent and predictable results for language applications, independent of the language in which they are written.

Language Environment is the prerequisite run-time environment for applications generated with the following IBM compiler products:

- z/OS C/C++
- OS/390® C/C++
- C/C++ Compiler for MVS/ESA™
- C/C++ Compiler for z/VM
- AD/Cycle® C/370™ Compiler
- VisualAge for Java, Enterprise Edition for OS/390
- Enterprise COBOL for z/OS
- COBOL for OS/390 & VM
- COBOL for MVS & VM (formerly COBOL/370)
- Enterprise PL/I for z/OS and OS/390
- VisualAge PL/I for OS/390
- PL/I for MVS & VM (formerly PL/I MVS™ & VM)
- VS FORTRAN and FORTRAN IV (in compatibility mode)

**Restrictions:** The following restrictions apply to z/OS.e:

- The following compilers are not licensed for use on z/OS.e:
  - COBOL
  - PL/I
  - FORTRAN
- The following subsystems are not licensed for use on z/OS.e:
  - CICS
  - IMS™
- Execution of applications written in the following languages is not functionally supported on z/OS.e:
  - COBOL (except for precompiled COBOL DB2® stored procedures and other precompiled COBOL applications using the Language Environment preinitialization interface
  - FORTRAN
- The following are not functional and/or not licensed for use on z/OS.e:
  - Language Environment Library Routine Retention (LRR)
  - Language Environment compatibility preinitialization for C and PL/I
- Customers are not permitted to use lower levels of Language Environment on z/OS.e.

Language Environment supports, but is not required for, an interactive debug tool for debugging applications in your native z/OS environment. The IBM interactive Debug Tool is available with z/OS, or with the latest releases of the C/C++, COBOL, PL/I and VisualAge for Java compiler products.
Language Environment supports, but is not required for, VS Fortran Version 2 compiled code (z/OS only).

Language Environment consists of the common execution library (CEL) and the run-time libraries for C/C++, COBOL, Fortran, and PL/I.

For more information on VisualAge for Java, Enterprise Edition for OS/390, program number 5655-JAV, see the product documentation.

Using your documentation

The publications provided with Language Environment are designed to help you:

- Manage the run-time environment for applications generated with a Language Environment-conforming compiler.
- Write applications that use the Language Environment callable services.
- Develop interlanguage communication applications.
- Customize Language Environment.
- Debug problems in applications that run with Language Environment.
- Migrate your high-level language applications to Language Environment.

Language programming information is provided in the supported high-level language programming manuals, which provide language definition, library function syntax and semantics, and programming guidance information.

Each publication helps you perform different tasks, some of which are listed in Table 1. All books are available in printable (PDF) and BookManager softcopy formats. For a complete list of publications that you may need, see “Bibliography” on page 635.

How to read syntax diagrams

This section describes how to read syntax diagrams. It defines syntax diagram symbols, items that may be contained within the diagrams (keywords, variables, delimiters, operators, fragment references, operands) and provides syntax examples that contain these items.

Syntax diagrams pictorially display the order and parts (options and arguments) that comprise a command statement. They are read from left to right and from top to bottom, following the main path of the horizontal line.

Symbols

The following symbols may be displayed in syntax diagrams:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>➞</td>
<td>Indicates the beginning of the syntax diagram.</td>
</tr>
<tr>
<td>➔</td>
<td>Indicates that the syntax diagram is continued to the next line.</td>
</tr>
<tr>
<td>➞</td>
<td>Indicates that the syntax is continued from the previous line.</td>
</tr>
<tr>
<td>➔</td>
<td>Indicates the end of the syntax diagram.</td>
</tr>
</tbody>
</table>

Syntax items

Syntax diagrams contain many different items. Syntax items include:

- Keywords - a command name or any other literal information.
- Variables - variables are italicized, appear in lowercase and represent the name of values you can supply.
- Delimiters - delimiters indicate the start or end of keywords, variables, or operators. For example, a left parenthesis is a delimiter.
- Operators - operators include add (+), subtract (-), multiply (*), divide (/), equal (=), and other mathematical operations that may need to be performed.
- Fragment references - a part of a syntax diagram, separated from the diagram to show greater detail.
- Separators - a separator separates keywords, variables or operators. For example, a comma (,) is a separator.

Note: If a syntax diagram shows a character that is not alphanumeric (for example, parentheses, periods, commas, equal signs, a blank space), enter the character as part of the syntax.
Keywords, variables, and operators may be displayed as required, optional, or default. Fragments, separators, and delimiters may be displayed as required or optional.

<table>
<thead>
<tr>
<th>Item type</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required</td>
<td>Required items are displayed on the main path of the horizontal line.</td>
</tr>
<tr>
<td>Optional</td>
<td>Optional items are displayed below the main path of the horizontal line.</td>
</tr>
<tr>
<td>Default</td>
<td>Default items are displayed above the main path of the horizontal line.</td>
</tr>
</tbody>
</table>

**Syntax examples**

The following table provides syntax examples.

<table>
<thead>
<tr>
<th>Item</th>
<th>Syntax example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Required item.</td>
<td></td>
</tr>
<tr>
<td>Required items appear on the main path of the horizontal line.</td>
<td></td>
</tr>
<tr>
<td>You must specify these items.</td>
<td></td>
</tr>
<tr>
<td>Required choice.</td>
<td></td>
</tr>
<tr>
<td>A required choice (two or more items) appears in a vertical stack on the main path of the horizontal line. You must choose one of the items in the stack.</td>
<td></td>
</tr>
<tr>
<td>Optional item.</td>
<td></td>
</tr>
<tr>
<td>Optional items appear below the main path of the horizontal line.</td>
<td></td>
</tr>
<tr>
<td>Optional choice.</td>
<td></td>
</tr>
<tr>
<td>An optional choice (two or more items) appears in a vertical stack below the main path of the horizontal line. You may choose one of the items in the stack.</td>
<td></td>
</tr>
<tr>
<td>Default.</td>
<td></td>
</tr>
<tr>
<td>Default items appear above the main path of the horizontal line.</td>
<td></td>
</tr>
<tr>
<td>The remaining items (required or optional) appear on (required) or below (optional) the main path of the horizontal line. The following example displays a default with optional items.</td>
<td></td>
</tr>
<tr>
<td>Variable.</td>
<td></td>
</tr>
<tr>
<td>Variables appear in lowercase italics. They represent names or values.</td>
<td></td>
</tr>
<tr>
<td>Repeatable item.</td>
<td></td>
</tr>
<tr>
<td>An arrow returning to the left above the main path of the horizontal line indicates an item that can be repeated.</td>
<td></td>
</tr>
<tr>
<td>A character within the arrow means you must separate repeated items with that character.</td>
<td></td>
</tr>
<tr>
<td>An arrow returning to the left above a group of repeatable items indicates that one of the items can be selected, or a single item can be repeated.</td>
<td></td>
</tr>
</tbody>
</table>
Table 2. Syntax examples (continued)

<table>
<thead>
<tr>
<th>Item</th>
<th>Syntax example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fragment.</td>
<td>The - fragment - symbol indicates that a labelled group is described below the main syntax diagram. Syntax is occasionally broken into fragments if the inclusion of the fragment would overly complicate the main syntax diagram.</td>
</tr>
</tbody>
</table>

This Programming Guide

To use this book you should be familiar with the Language Environment product and one or more of the supported Language Environment-conforming high-level languages listed above. The term C/C++ is used generically to refer to information that applies to both C and C++.

Previous versions of the Language Environment-conforming language products provided their own environment and services for running applications, and their associated application programming guides including information on how to link-edit and run applications. Language Environment now provides the run-time support required to run applications compiled under all of the Language Environment-conforming HLLs, as well as the facility for interlanguage communication between supported languages.

For application programming, you will need to use this book and [z/OS Language Environment Programming Reference]. This book contains information about linking, running, and using services within the Language Environment environment, the Language Environment program management model, and language- and operating system-specific information, where applicable. [z/OS Language Environment Programming Reference] contains more detailed information, as well as specific syntax for using run-time options and callable services. [z/OS Language Environment Writing Interlanguage Communication Applications] provides information to help you create and run interlanguage communication (ILC) applications.

This book is organized as follows:

- Part 1 includes a basic introduction to Language Environment. It also describes linking, loading, and running under each of the supported operating systems, as well as using IBM-supplied cataloged procedures, Language Environment run-time options, and Language Environment callable services.
- Part 2 describes how to prepare an application to run in Language Environment.
- Part 3 describes Language Environment concepts, services, and models, including initialization and termination, program management model, storage, condition handling, messages, callable services, and math services.
- Part 4 explains using interfaces to other products such as CICS, DB2, and IMS.
- Part 5 addresses specialized programming tasks, such as using run-time user exits, assembler considerations, preinitialization services, and using nested enclaves.
• The various appendixes describe interfaces to subsystems, writing callable services, using parameter list formats, prelinking, using the C object library, systems programming environments, sort and merge considerations, ISPF, and Language Environment macros.

Determining if a publication is current

As needed, IBM changes its information. For a given book, updates to the hardcopy and associated BookManager® softcopy are usually available at the same time. Sometimes, however, the updates to hardcopy and softcopy are available at different times. Here’s how to determine if you are looking at the most current copy of a book:

1. At the end of the order number there is a dash followed by two digits, often called the dash level. A book with a higher dash level is more current than one with a lower dash level. For example, in the book order number SC28-1939-01, the dash level 01 means that the book is more current than previous levels, such as 00.

2. If a hardcopy book and a softcopy book have the same dash level, it is possible that the softcopy book is more current than the hardcopy book. Check the dates shown in the Summary of Changes. The softcopy book might have a more recently dated Summary of Changes than the hardcopy book.

3. To compare softcopy books, you can check the last two characters of the softcopy filename (also called the book name). The higher the number, the more recent the book. For example, IEA4E802 is more recent than IEA4E801. Also, an asterisk next to the book titles in the CD-ROM booklet and the readme files indicates that a publication is either new or has been changed.

Where to find more information

Please see z/OS Information Roadmap for an overview of the documentation associated with z/OS, including the documentation available for z/OS Language Environment.

Accessing z/OS licensed documents on the Internet

z/OS™ licensed documentation is available on the Internet in PDF format at the IBM Resource Link™ Web site at:

http://www.ibm.com/servers/resourcelink

Licensed documents are available only to customers with a z/OS license; access to these documents requires an IBM Resource Link user ID and password, and a key code. Based on which offering you chose (ServerPac, CBPDO, SystemPac), information concerning the key code is available in the Installation Guide that is delivered with z/OS and z/OS.e orders as follows:

• ServerPac Installing Your Order
• CBPDO Memo to Users Extension
• SystemPac Installation Guide

To obtain your IBM Resource Link user ID and password, log on to:

http://www.ibm.com/servers/resourcelink

To register for access to the z/OS licensed documents:

1. Sign in to Resource Link using your Resource Link user ID and password.
2. Select User Profiles located on the left-hand navigation bar.
Note: You cannot access the z/OS licensed documents unless you have registered for access to them and received an e-mail confirmation informing you that your request has been processed.

Printed licensed documents are not available from IBM.

You can use the PDF format on either z/OS Licensed Product Library CD-ROM or IBM Resource Link to print licensed documents.

Using LookAt to look up message explanations

LookAt is an online facility that lets you look up explanations for most of the IBM messages you encounter, as well as for some system abends and codes. Using LookAt to find information is faster than a conventional search because in most cases LookAt goes directly to the message explanation.

You can use LookAt from the following locations to find IBM message explanations for z/OS elements and features, z/VM®, VSE/ESA™, and Clusters for AIX® and Linux:

- The Internet. You can access IBM message explanations directly from the LookAt Web site at [http://www.ibm.com/eserver/zseries/zos/bkserv/lookat/]
- Your z/OS TSO/E host system. You can install code on your z/OS or z/OS.e systems to access IBM message explanations, using LookAt from a TSO/E command line (for example, TSO/E prompt, ISPF, or z/OS UNIX® System Services running OMVS).
- Your Microsoft® Windows® workstation. You can install code to access IBM message explanations on the z/OS Collection (SK3T-4269), using LookAt from a Microsoft Windows command prompt (also known as the DOS command line).
- Your wireless handheld device. You can use the LookAt Mobile Edition with a handheld device that has wireless access and an Internet browser (for example, Internet Explorer for Pocket PCs, Blazer, or Eudora for Palm OS, or Opera for Linux handheld devices). Link to the LookAt Mobile Edition from the LookAt Web site.

You can obtain code to install LookAt on your host system or Microsoft Windows workstation from a disk on your z/OS Collection (SK3T-4269), or from the LookAt Web site (click Download, and select the platform, release, collection, and location that suit your needs). More information is available in the LOOKAT.ME files available during the download process.

Information updates on the web

For the latest information updates that have been provided in PTF cover letters and Documentation APARs for z/OS and z/OS.e, see the online document at:

`publibz.boulder.ibm.com/cgi-bin/bookmgr_OS390/BOOKS/ZIDOCMST/CCONTENTS`

This document is updated weekly and lists documentation changes before they are incorporated into z/OS publications.
Summary of changes

Summary of Changes
for SA22-7561-05
z/OS Version 1 Release 6

This document contains information previously presented in z/OS Language Environment Programming Guide SA22-7561-04, which supported z/OS Version 1 Release 5.

The following summarizes the changes to that information.

New Information
- "CEEPCALL Macro — Call a Language Environment-Conforming Routine" on page 499
- "CEEPDDA Macro — Define a Data Item in the Writeable Static Area (WSA)" on page 501
- "CEEPLDA Macro — Returns the Address of a Data Item Defined by CEEPDDA" on page 503
- z/OS Batch added for DLL support, see "Support for DLLs" on page 43
- Definitions added, see "DLL Concepts and Terms" on page 44
- Information on loading DLLs added, see "Loading a DLL" on page 45.

Changed Information
- The heappools cell size maximum has been increased. For more information, see "Using HEAPPOOLS to improve performance" on page 173.

This document contains terminology, maintenance, and editorial changes. Technical changes or additions to the text and illustrations are indicated by a vertical line to the left of the change.

Starting with z/OS V1R2, you may notice changes in the style and structure of some content in this document — for example, headings that use uppercase for the first letter of initial words only, and procedures that have a different look and format. The changes are ongoing improvements to the consistency and retrievability of information in our documents.

Summary of Changes
for SA22-7561-04
z/OS Version 1 Release 5

This document contains information previously presented in z/OS Language Environment Programming Guide SA22-7561-03, which supported z/OS Version 1 Release 4.

The following summarizes the changes to that information.

Changed Information
- Information on loading DLLs has been updated. For more information, see "Loading DLLs" on page 52.
• C and C++ compatibility considerations for using run-time options have been updated. For more information, see "C and C++ Compatibility Considerations" on page 122.

• The heappools cell size maximum has been increased. For more information, see "Using HEAPPOOLS to improve performance" on page 173.

• The CEELOAD and CEEFETCH macro examples have been updated. For more information, see "CEELOAD Macro — Dynamically Load a Language Environment-Conforming Routine" on page 491 and "CEEFETCH Macro — Dynamically Load a Language Environment-Conforming Routine" on page 494.

• Stop semantics information for preinitialization services has been updated. For more information, see "Stop semantics" on page 521.

• Sections of the Preinitialization chapter have updated return codes and usage notes. For more information, see "Preinitialization interface" on page 522.

Summary of Changes for SA22-7561-03
z/OS Version 1 Release 4

This document contains information previously presented in z/OS Language Environment Programming Guide SA22-7561-02, which supported z/OS Version 1 Release 3.

The following summarizes the changes to that information.

New Information
• Information is added to indicate this document supports z/OS.e.

Changed Information
• The Preinitialization chapter has been updated. For more information, see Chapter 30, "Using preinitialization services," on page 515.

Summary of Changes for SA22-7561-02
z/OS Version 1 Release 3

This document contains information previously presented in z/OS Language Environment Programming Guide SA22-7561-01, which supported z/OS Version 1 Release 2.

The following summarizes the changes to that information.

New Information
• Language Environment now provides support for an alternative Vendor Heap Manager (VHM). For more information, see "Alternative Vendor Heap Manager" on page 190.

• Applications defined in the preinitialization table can now be XPLINK supported if the customer selects to run in an XPLINK environment. For more information, see "Preinit XPLINK considerations" on page 519.

• An appendix with z/OS product accessibility information has been added.

Changed Information
• A new signal, SIGDANGER, has been added to the condition tokens table. For more information, see "Run-Time Messages with POSIX" on page 322.
• Enterprise COBOL for z/OS and OS/390 supports running COBOL programs in multiple threads. Updates were made to reflect the COBOL multithreading support provided by Language Environment. For more information, see "Asynchronous Interrupts" on page 478.

• Users are now allowed to replace the storage management routines without having to also provide the program management routines. For more information, see "Service routines" on page 542.

Summary of Changes
for SA22-7561-01
z/OS Version 1 Release 2

This document contains information previously presented in z/OS Language Environment Programming Guide SA22-7561-00, which supported z/OS Version 1 Release 1.

The following summarizes the changes to that information.

New Information
• A new run-time option, FILETAG, is used to specify whether HFS files are automatically converted from ASCII to EBCDIC, and whether files are automatically tagged with a coded character set when they are opened.
• You can now use the HEAPCHK run-time option to help identify storage leaks.

Changed Information
• The defaults for some of the run-time options have changed. See Figure 49 on page 125 and z/OS Language Environment Programming Reference.
Part 1. Creating Applications with Language Environment

This section explains the steps for creating and running an executable program, and provides an overview of run-time options.

**Note:** The terms in this section having to do with linking (*bind, binding, link, link-edit, and so forth*) refer to the process of creating an executable program from object modules (the output produced by compilers and assemblers). The program used is the DFSMS program management binder. The binder extends the services of the linkage editor and is the default program provided for creating an executable. For linkage editor-specific information, see [z/OS DFSMS Program Management](https://www.ibm.com/support/docview.ws/docid/105828).

If you have an application that contains interlanguage calls, you might need to relink-edit it to take advantage of the Language Environment ILC support. See [z/OS Language Environment Run-Time Application Migration Guide](https://www.ibm.com/support/docview.wss?uid=swg27046551) for more information.
Chapter 1. Introduction to Language Environment

Language Environment provides a common run-time environment for IBM versions of certain high-level languages (HLLs), namely, C, C++, COBOL, Fortran, and PL/I, in which you can run existing applications written in previous versions of these languages as well as in the current Language Environment-conforming versions. Prior to Language Environment, each of the HLLs had to provide a separate run-time environment.

Language Environment combines essential and commonly used run-time services, such as routines for run-time message handling, condition handling, storage management, date and time services, and math functions, and makes them available through a set of interfaces that are consistent across programming languages. With Language Environment, you can use one run-time environment for your applications, regardless of the application’s programming language or system resource needs because most system dependencies have been removed.

Language Environment provides compatible support for existing HLL applications; most existing single-language applications can run under Language Environment without being recompiled or relink-edited. POSIX-conforming C applications can use all Language Environment services.

Components of Language Environment

As Figure 1 on page 4 shows, Language Environment consists of the following components:

- Basic routines that support starting and stopping programs, allocating storage, communicating with programs written in different languages, and indicating and handling error conditions.
- Common library services, such as math services and date and time services, that are commonly needed by programs running on the system. These functions are supported through a library of callable services.
- Language-specific portions of the common run-time library.
The following IBM Language Environment-conforming language compilers currently participate in this release:
- z/OS C/C++
- C/C++ Compiler for MVS/ESA
- AD/Cycle C/370 Compiler
- VisualAge for Java, Enterprise Edition for OS/390
- Enterprise COBOL for z/OS and OS/390
- COBOL for OS/390 & VM
- COBOL for MVS & VM (formerly COBOL/370)
- VisualAge PL/I for OS/390
- PL/I for MVS & VM (formerly PL/I MVS & VM)
- VS FORTRAN and FORTRAN IV (in compatibility mode)

See z/OS Language Environment Run-Time Application Migration Guide and z/OS and z/OS.e Planning for Installation for a list of pre-Language Environment IBM language products.

Common Run-Time Environment of Language Environment

Figure 2 on page 5 illustrates the common environment that Language Environment creates.
Figure 2. Language Environment’s Common Run-Time Environment
Chapter 2. Preparing to Link-Edit and Run under Language Environment

This chapter discusses what you need to know before link-editing and running applications under Language Environment. After Language Environment is installed on your system, you should run an existing application under Language Environment. Although you may need to link-edit to different libraries, the procedure is similar to that used in pre-Language Environment versions of C, COBOL, Fortran, or PL/I. For more information about running applications under Language Environment that have not been linked with Language Environment, see the individual language migration guides, such as Enterprise COBOL for z/OS Migration Guide.

To help you get started, this chapter describes the following common link-edit and run tasks, which you might want to try before reading further:

- Link-editing and running an existing object module and accepting the default Language Environment run-time options
- Link-editing and running an existing object module and specifying new Language Environment run-time options
- Calling a Language Environment service

Note that several Fortran and C library routines have identical names. This chapter describes what you must do to resolve any potential conflicts in using these names.

This chapter also describes basic tasks intended to help give you an idea of what running an application under Language Environment is like. It is not intended to illustrate every aspect of link-editing and running you might want to learn. Detailed instructions about link-editing and running existing and new applications under each supported operating system are provided in subsequent chapters, and in z/OS DFSMS Program Management.

Understanding the Basics

Language Environment library routines are divided into two categories: resident routines and dynamic routines. The resident routines are linked with the application and include such things as initialization/termination routines and pointers to callable services. The dynamic routines are not part of the application and are dynamically loaded during run time.

The way Language Environment code is packaged keeps the size of application executable programs small. When maintaining dynamic library code, you need not relink-edit the application code except under special circumstances, such as when you use an earlier version of code.

The linkage editor converts an object module into an executable program and stores it in a library. The executable program can then be run from that library at any time. The link-edit process combines output from compilers, language translators, link-edit programs and control statements to produce an executable program (load module or program object) and stores it in a library (PDS, PDSE, or HFS). The executable program can then be run from that library. Either the program management binder or linkage editor can be used to perform the link-edit process. All of the services of the linkage editor can be performed by the binder. In addition, the binder provides additional functionality and usability improvements. See z/OS
Prefering to Use Language Environment

[DFSM Program Management] for a complete discussion of services to create, load, modify, list, read, transport and copy executable programs.

Planning to Link-Edit and Run

There are certain considerations that you must be aware of before link-editing and running applications under Language Environment.

Language Environment resident routines for non-XPLINK applications, including those for callable services, initialization, and termination, are located in the SCEELKED and SCEELKEX libraries. Language Environment resident routines for XPLINK applications are located in the SCEEBIND and SCEEBND2 libraries. Language Environment dynamic routines are located in the SCEERUN and SCEERUN2 libraries. The Language Environment libraries are located in data sets identified with a high-level qualifier specific to the installation.

The following is a summary of the Language Environment libraries and their contents:

SCEERUN
A PDS which contains the run-time library routines needed during execution of applications written in C/C++, PL/I, COBOL and FORTRAN.

SCEERUN2
A PDSE which contains the run-time library routines needed during execution of applications written in C/C++ and COBOL.

SCEELKED
Contains Language Environment resident routines for non-XPLINK applications, including those for callable services, initialization, and termination. This includes language-specific callable services, such as those for the C/C++ run-time library. Only case-insensitive names of eight or less characters in length are contained in this library. This library must be used only when link-editing a non-XPLINK program.

SCEELKEX
Like SCEELKED, contains Language Environment resident routines for non-XPLINK applications. However, case-sensitive names which can be greater than eight characters in length are contained in this library. This allows symbols such as the C/C++ printf and pthread_create functions to be resolved without requiring the names to be uppercased, truncated, or mapped to another symbol. This library must be used only when link-editing a non-XPLINK program.

SCEEOBJ
Contains Language Environment resident definitions for non-XPLINK applications which may be required for z/OS UNIX System Services (z/OS UNIX) programs, such as the definition of the external variable symbol environ. SCEEOBJ must be used whenever link-editing a z/OS UNIX non-XPLINK program.

SCEECPP
Contains Language Environment resident definitions for non-XPLINK applications which may be required for C++ programs, such as the definition of the new operator. SCEECPP must be used whenever link-editing a program which includes any NOXPLINK-compiled C++ object modules.

SCEEBIND
Contains Language Environment resident routines for XPLINK applications, but is deprecated and may not be supported in a future release. Use SCEEBND2 instead.
SCEEBND2
Contains all Language Environment resident routines for XPLINK applications. This one library replaces the four libraries of resident routines for non-XPLINK applications. For XPLINK, this one library is used wherever the above four libraries of resident routines (SCEELKED, SCEELKEX, SCEEOBJ, SCEECPP) had been used. It provides only a small number of resident routines, since most of the functions formerly provided in those static libraries are instead provided using dynamic linkage. **SCEEBND2 must be used only when link-editing an XPLINK program.**

SCEELIB
Contains side-decks for DLLs provided by Language Environment.

Many of the language-specific callable services available to XPLINK-compiled applications appear externally as DLL functions. See Chapter 4, “Building and Using Dynamic Link Libraries (DLLs),” on page 43 for information about DLLs. To resolve these references from XPLINK applications, a definition side-deck must be included when link-editing the application. The SCEELIB library contains the following side-decks in support of XPLINK:

- **CELHS001** — Side-deck to resolve references to Language Environment services when link-editing an XPLINK application. This includes both Application Writer Interfaces (AWIs, see [z/OS Language Environment Programming Reference](https://www.ibm.com/support/knowledgecenter/SSEQYV_5.4.0/com.ibm.zos.v5r4.doc/ct/ceewri什么是.html)) and Compiler Writer Interfaces (CWIs, see [z/OS Language Environment Vendor Interfaces](https://www.ibm.com/support/knowledgecenter/SSEQYV_5.4.0/com.ibm.zos.v5r4.doc/ct/ceewri什么是.html)). The entries in this side-deck replace the corresponding non-XPLINK resident routines in SCEELKED.
  
  The AWI stubs also exist as executables in SCEERUN, which can be loaded and run from non-XPLINK applications. This technique cannot be used with XPLINK applications.

- **CELHS003** — Side-deck to resolve references to callable services in the C/C++ run-time library when link-editing an XPLINK application. The entries in this side-deck replace the corresponding non-XPLINK resident routines in SCEELKEX, SCEELKED and SCEEOBJ.

- **CELHSCPP** — Side-deck to resolve references to C++ run-time library (RTL) definitions that may be required when link-editing an XPLINK application. The entries in this side-deck replace the non-XPLINK resident routines in SCEECPP.
  
  The functions in these side-decks can be called from an XPLINK application. However, they cannot be used as the target of an explicit `dllqueryfn()` against the DLL.

**Link-Editing Single-Language Applications**

The default main entry point for a C, C++, or PL/I application is CEESTART (PLISTART for code compiled with OS PL/I); for a Fortran application, it is the name of the main routine. For COBOL, the main entry point for an application is determined in one of two ways:

- The name of the first object module presented to the link-edit process.
- Explicit specification of the entry point by providing a control statement to the link-edit process.

A copy of CEESTART resides in the Language Environment SCEELKED library. Do not explicitly include it in the link-edit process, even for Language Environment-conforming languages. The compilers generate CEESTART or references to it when necessary.
Preparing to Use Language Environment

Although CEESTART is not used as an entry point by Language Environment-conforming assembler programs, it still must be resolved by the link-editor. To ensure this is possible, avoid using the NCAL link-editor option.

You must link-edit applications before you run them.

Link-Editing ILC Applications

When mixing languages within an application, presenting the desired main routine to the link-edit process first nominates it as the entry point. You can specify only one main routine.

To get Language Environment’s support in using pre-Language Environment C – COBOL ILC applications, you must relink-edit these applications to replace old HLL library routines with Language Environment routines. Relink-editing ILC applications of any language combination is usually required, with the following exceptions:

- Any PL/I – COBOL ILC applications relink-edited using the migration aid provided by OS PL/I Version 2 Release 3. (See VisualAge PL/I for OS/390 Compiler and Run-Time Migration Guide or Enterprise PL/I for z/OS and OS/390 Migration Guide for details.) The PTF numbers for the migration aid are UN76954 and UN76955.
- Any PL/I – C ILC applications.
- Any COBOL – C ILC applications relink-edited using the migration aid provided by the C/370 Version 2 Library. This migration aid was delivered in the fix for APAR PN74931.

For more information, see z/OS Language Environment Writing Interlanguage Communication Applications, z/OS Language Environment Run-Time Application Migration Guide and the migration guides for your primary HLL. (See “Bibliography” on page 635 for a list of the various migration guides.)

Downward Compatibility Considerations

As of OS/390 Version 2 Release 10, Language Environment provides downward compatibility support. Assuming that required programming guidelines and restrictions (see below) are observed, this support enables programmers to develop applications on higher release levels of the operating system, for deployment on execution platforms that are running lower release levels of the operating system. For example, you may use OS/390 V2R10 or later (and Language Environment) on a development system where applications are coded, link edited, and tested, while using any supported lower release of OS/390 (and Language Environment) on their production systems where the finished application modules are deployed.

Downward compatibility support is not the roll-back of new function to prior releases of the operating system. Applications developed exploiting the downward compatibility support must not use Language Environment function that is unavailable on the lower release of the operating system where the application will be deployed. The downward compatibility support includes toleration PTFs for lower releases of the operating system (specific PTF numbers can be found in the PSP buckets), to assist in diagnosis of applications that violate the programming requirements for this support.

The downward compatibility support provided by OS/390 V2R10 and later, and by the toleration PTFs, does not change Language Environment’s upward compatibility. That is, applications coded and link-edited with one release of Language
Preparing to Use Language Environment

Environment will continue to execute on later releases of Language Environment, without a need to recompile or relink-edit the application, independent of the downward compatibility support.

The application requirements and programming guidelines for downward compatibility are:

- The application must only use Language Environment function that is available on the release level of the operating system used on the target deployment system.
- The application must only use Language Environment function that is available on the release level of the operating system used for developing and link-editing the application, by using the appropriate Language Environment object libraries, header files, and macros.
- The release level of the operating system used for application development and link-editing must be at least the level that is the prerequisite of the compiler product(s) (C/C++, COBOL, Fortran, PL/I) that are used to develop the application.
- The release level of the operating system used on the target deployment system must be at least the level that is the prerequisite of the compiler product(s) that are used to develop the application.
- The release level of the operating system used for application development and link-editing must be at least OS/390 V2R10.
- The program object format of the application must be no greater than the highest level supported on the target deployment system.

The term "Language Environment function" used in the discussion of downward compatibility support refers to:

- Language Environment callable services (see z/OS Language Environment Programming Reference).
- Language Environment run-time options
- C/C++ library functions
- UNIX branding functions
- Other new language functionality that has an explicit operating system release prerequisite that is documented in the user publications. For example, with OS/390 V2R9 Language Environment, new support was added so that COBOL programs could dynamically call a reentrant C routine with constructed reentrancy without using #pragma(xxx,C080L). This support is available on OS/390 V2R9 Language Environment or later, but is not available on prior releases.

The compiler products that support development of downward compatible applications are listed in the table below, along with their prerequisite minimum release level of the operating system. (Note that prior releases of the compilers beyond those listed in the table are still supported by Language Environment, but do not provide downward compatibility. They only support upward compatibility.)
Preparing to Use Language Environment

Table 3. Prerequisite OS/390 Release Level for the Various Compilers that Support Downward Compatibility

The diagnosis assistance that will be provided by the toleration PTFs includes:

- **Options Processing:** Whenever an application exploits Language Environment run-time options that are unavailable on the release of the operating system the application is executed on, a message will be issued. In order to issue this message, toleration PTFs are available down to OS/390 V2R6, and you must apply them on the target system. The use of environment variables, even specific Language Environment ones, is not covered by this support.

- **Detection of unsupported function:** In many cases where a programmer disregards the requirements and programming guidelines and exploits a Language Environment function that is unavailable on the release of the operating system the application is executed on, Language Environment will raise a new condition. With an unhandled condition, the application is terminated. In order to raise this new condition, toleration PTFs are available down to OS/390 V2R6, and you must apply them on the target system.

- **C/C++ headers:** As of OS/390 V2R10, support has been added to the C/C++ headers shipped with Language Environment to allow application developers to "target" a specific release, in order to ensure the application hasn't taken advantage of any new C/C++ library function. See the z/OS C/C++ User's Guide for details of how the TARGET compiler option can be used to create downward-compatible applications and prevent application developers from using new C/C++ library functions in applications.

- **Detection of unsupported program object format:** If the program object format is at a level which is not supported by the target deployment system, then the deployment system will produce an abend when trying to load the application program. The abend will indicate that DFSMS/MVS® was unable to find or load the application program. Correcting this problem does not require the installation of any toleration PTFs. Rather the application developer will need to recreate the program object which is compatible with older deployment system. For information on using the Program Management binder COMPAT option, see z/OS MVS Program Management: User’s Guide and Reference.

**Note:** Program objects created by the c89 utility will use the default COMPAT=CURRENT, whereas the Program Management binder invoked natively will use the default COMPAT=MIN.
Checking Which Run-Time Options Are in Effect

Using the Language Environment run-time option RPTOPTS, you can control whether a run-time options report is produced; with the Language Environment run-time option MSGFILE, you can control where report output is directed. RPTOPTS generates a report of all the run-time options that are in effect when your application begins to run. The IBM-supplied default for RPTOPTS is OFF, meaning a report is not generated when your application finishes running. If you override the default setting of RPTOPTS in any of the ways described below, a report is sent to the default location:

- On MVS, to the standard system data set SYSOUT. SYSOUT is dynamically allocated when needed, and is directed to whatever MSGCLASS you specified on the JOB card when you ran the application.
- Under z/OS UNIX, it goes to file descriptor 2.
- On TSO/E, to SYSOUT.

If you want to change the options report destination, you can alter the default setting of the MSGFILE run-time option, which specifies where all run-time diagnostics and messages are written. For example, if you specify MSGFILE(OPTRPRT), the storage report is written to a file whose ddname is OPTRPRT. You need to allocate a data set for OPTRPRT under batch and TSO/E.

For the syntax of RPTOPTS and MSGFILE, see z/OS Language Environment Programming Reference

HLL Compatibility Considerations

Some applications link-compiled with previous levels of HLL run-time libraries might have to be relink-compiled with Language Environment. Language Environment provides sample JCL and EXECs to help you replace pre-Language Environment library routines in your applications with equivalent Language Environment routines. For example:

- The COBOL library routine replacement tools IGZWRK LA, IGZWRK KB and IGZWRK KC, located in SCEESAMP, can be used to replace OS/VS COBOL and VS COBOL II library routines in a COBOL executable module with the equivalent Language Environment routines.
  - IGZWRK LA – relink a VS COBOL II program.
  - IGZWRK KB – relink a OS/VS COBOL program.
  - IGZWRK KC – relink a program that contains both VS COBOL II and OS/VS COBOL.

See "COBOL Considerations" on page 14 for details.

- The PL/I library routine replacement tools IBMWRK L and IBMWRK KC, located in SCEESAMP, can be used to replace OS PL/I library routines in an OS PL/I executable program with the equivalent Language Environment routines. See "PL/I Considerations" on page 24 for details.

- The Fortran library module replacement tool, AFHWRLK, also located in SCEESAMP, can be used to replace VS FORTRAN Version 1 and VS FORTRAN Version 2 run-time library modules with the equivalent Language Environment modules. See "Fortran Considerations" on page 15 for details.

For information on compatibility considerations for a pre-Language Environment library routine, consult the migration guide for the HLL of the routine. A list of the HLL migration guides can be found in "Bibliography" on page 635.
C/C++ AMODE/RMODE Considerations

The following table shows valid AMODE and RMODE combinations when the C/C++ run-time product is installed with the run-time library, EDCZV, having RMODE=ANY. These settings are the installation defaults. XPLINK executable programs always run with AMODE=31.

<table>
<thead>
<tr>
<th>Product</th>
<th>RMODE</th>
<th>AMODE</th>
<th>Notes</th>
</tr>
</thead>
<tbody>
<tr>
<td>C/C++ with CICS/ESA®</td>
<td>ANY</td>
<td>31</td>
<td>All programs must use this AMODE and RMODE combination.</td>
</tr>
<tr>
<td>C/C++ with COBOL</td>
<td>24 or ANY</td>
<td>31</td>
<td>For VS COBOL II, all COBOL programs must be compiled with the RES compiler option, which causes AMODE=31. For COBOL for OS/390 &amp; VM, COBOL for MVS &amp; VM and COBOL/370, AMODE=31 always.</td>
</tr>
<tr>
<td>C/C++ with DB2 R2.2</td>

<td>All programs must use this AMODE and RMODE combination.</td>
</tr>
<tr>
<td>C/C++ with IMS/ESA® V3R1</td>
<td>24 or ANY</td>
<td>31</td>
<td>All programs must use the same AMODE and RMODE combination. There are no restrictions on IMS/ESA parameters.</td>
</tr>
<tr>
<td>One of the following:</td>
<td>24 or ANY</td>
<td>31</td>
<td>All programs must use the same AMODE and RMODE combination.</td>
</tr>
<tr>
<td>• C/C++ only</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• C/C++ with ISPF</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>• C/C++ with PL/I</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

For information on AMODE switching, see [z/OS C/C++ Run-Time Library Reference](#).

COBOL Considerations

This section describes what you need to know if you link-edit or relink-edit a COBOL program with Language Environment.

Replacing COBOL Library Routines in a COBOL Load Module

Three sample jobs are provided in the SCEESAMP sample library that can be used to replace all OS/VS COBOL and VS COBOL II library routines in load modules containing OS/VS COBOL and VS COBOL II programs. These sample jobs are:

- IGZWRRLKA to relink-edit a VS COBOL II load module with Language Environment®
- IGZWRRLKB to relink-edit an OS/VS COBOL load module with Language Environment
- IGZWRRLKC to relink-edit a load module that contains both OS/VS COBOL programs and VS COBOL II programs with Language Environment

For more information on relink-editing existing OS/VS COBOL and VS COBOL II load modules, see [Enterprise COBOL for z/OS Migration Guide](#).

Using Language Environment Resident Routines for Callable Services

For COBOL CALL literal statements, the compiler allows you to specify whether your program uses static or dynamic calls to Language Environment callable services (or other subroutines):
Preparing to Use Language Environment

- When a COBOL program makes a static call to a Language Environment callable service, the Language Environment resident routine (a callable service stub) is link-edited with the program.
- When a COBOL program makes a dynamic call to a Language Environment callable service, the Language Environment resident routine is not link-edited with the program.

Only COBOL programs compiled with Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM or COBOL/370 can call Language Environment callable services.

**Note:** You can use dynamic calls from VS COBOL II programs to Language Environment Date/Time callable services. You cannot use dynamic call from VS COBOL II programs to other Language Environment callable services. You cannot use static calls from VS COBOL II programs to any Language Environment callable services.

For more information about COBOL static and dynamic calls, see [Enterprise COBOL for z/OS Programming Guide](#) or [COBOL for OS/390 & VM Programming Guide](#).

For more information on Language Environment callable services, which can be used by COBOL, see [z/OS Language Environment Programming Reference](#).

**Fortran Considerations**

This section discusses what you need to know if you link-edit or relink-edit a Fortran program.

**Replacing Fortran Run-Time Library Modules in a Fortran Executable Program**

To relink-edit your existing executable program under Language Environment, you must replace Fortran run-time library modules in the executable program with the equivalent Language Environment routines. The Fortran library module replacement tool enables you to do this without having to have the object modules that make up the executable program. This is most useful when:

- You need to recompile some, but not all, of your own Fortran routines that are within one of your executable programs.
- You need to upgrade existing programs to contain the Language Environment run-time library modules. Language Environment data sets can be installed, but the changes are not reflected in your own executable programs unless you link-edit them again using the updated data sets.

You might have to use your original executable program rather than your object modules as linkage editor input because you don’t have all of your routines available in source form for recompilation or because you didn’t retain the object modules. A problem occurs when you use your previous executable programs as linkage editor input because the linkage editor retains the non-Language Environment modules that are in your original executable program while including others from the current SYSLIB input. The solution is to use the Fortran library module replacement tool as discussed in the following section.
Using the Fortran Library Module Replacement Tool

The Fortran library module replacement tool provides a set of linkage editor REPLACE statements to help you replace all of the run-time library modules when your input to the linkage editor is an existing executable program containing the library modules. The tool supports executable programs created by VS FORTRAN Version 1, VS FORTRAN Version 2, and Language Environment. The source file containing the Fortran library module replacement tool is member AFHWRLK in the CEE.SCEESAMP library.

In Figure 3, the VS FORTRAN Version 2 run-time library modules in the executable program MYLMOD are replaced while retaining the compiled code, using the cataloged procedure CEEWL.

```
//RELINK EXEC PROC=CEEWL,PGMLIB=MYPDS.LOAD,GOPGM=MYLMOD
//SYSPRINT DD SYSOUT=A
//SAMPLIB DD DSN=CEE.SCEESAMP,DISP=SHR
//USERLMOD DD DSN=MYPDS.LOAD,DISP=OLD
//LKED.SYSIN DD *

     'MYPDS.LOAD(MYLMOD)'),  +
LOAD ('MYPDS.LOAD(MYLMOD)'),  +
LIB ('CEE.SCEELKED') NOTERM
```

Figure 4. Replacing VS FORTRAN Run-Time Library Modules under TSO/E, Using a CLIST

Resolving Static Common Block Name Conflicts

It is possible for a Fortran static common block name in one program unit to be in conflict with a Fortran intrinsic function name in another program unit. (A conflict could arise, for example, if you used LOG as a common block name and invoked the LOG intrinsic function in a different program unit.) To avoid any such conflict, either rename the common block or recompile with VS FORTRAN Version 2.5 or later.

It is also possible that a Fortran static common block name could conflict with another language's library routine name. (A conflict could arise, for example, if you used GETS as a common block name, and also invoked C's gets function.) If you find such a conflict, either:

- Change the common block to be dynamic (using the DC compiler option), or
- Change the name of the common block so it does not conflict with the other language's library routine name.
Resolving Library Module Name Conflicts between Fortran and C

Several Fortran and C library routines, shown in Table 4, have identical names. To correctly run applications that reference one or more of these names, you need to determine if a name conflict exists, and if so, to resolve it according to the prescription given in this section. Otherwise, a library routine other than the one you intend is likely to be linked into your executable program, and the results during execution will not be what you expect.

Before you proceed with this section, first resolve any static common block name conflicts as discussed in “Resolving Static Common Block Name Conflicts” on page 16.

Table 4. Fortran and C Library Routine Names that are Identical

<td>TANH</td>
</tr>
</tbody>
</table>

Conditions under Which Your Application Does Not Have a Name Conflict

If all three of the following conditions are true, your application does not have the name conflict discussed here, and you can therefore skip this section:

- The Language Environment interface validation exit is available. (The interface validation exit is a routine that, when used with the binder, automatically resolves conflicting library routine references within Fortran routines)
  - Under batch, this means any link-edit steps (for example, in cataloged procedures) have been changed to include EXITS(INTFVAL(CEEPINTV)) in the PARM parameter and to include the following DD statement:
    ```
    //STEPLIB DD DSN=CEE.SCEELKED,DISP=SHR
    ```
  - Under TSO/E, this means you have included EXITS(INTFVAL(CEEPINTV)) among your link-edit options. Use the TSO/E command TSOLIB to dynamically allocate a STEPLIB.
- You are not relink-editing a pre-Language Environment executable program in which none of the component parts have been changed, but instead are link-editing one or more individual routines.
- None of the routines you are link-editing is an assembler CSECT that references a Fortran library routine from the list in Table 4

Unless all three of the preceding conditions are true, you need to continue reading this section to be able to properly link-edit and run your application.

Determining If Your Application Has a Name Conflict

Examine Table 5. If your application contains a routine that is compiled (assembled) with one of the products shown in column one, and the routine uses one of the functions shown in column two, it has a name conflict that must be resolved.

Table 5. Conflicting Names per Product and Release

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>FORTRAN IV H Extended, or FORTRAN IV G1, or Assembler, any version</td>
<td>Any name in Table 4 on page 17</td>
</tr>
</tbody>
</table>

To determine how to resolve any name conflicts, determine which of the following conditions (labeled A through E) are true.

A The Language Environment interface validation exit is available, as described in “Conditions under Which Your Application Does Not Have a Name Conflict” on page 17.

B You have a fully executable program created with one or more pre-Language Environment products, and you are not modifying any of its component parts.

C Condition B is not true, and your application contains at least one assembler CSECT that references a conflicting name listed in Table 4 on page 17. You want the CSECT’s conflicting names resolved to Fortran routines.

D Condition B is not true, and your application consists only of one or more individual Fortran or assembler routines, of which at least one references a conflicting name. You want any conflicting names resolved to Fortran routines.

E Condition B is not true, and your application consists of one or more individual routines that are not just Fortran, assembler, or both. At least one Fortran or assembler routine references a conflicting name, and you want its conflicting names resolved to Fortran routines.

Next, find the row in Table 6 that corresponds to the combination of conditions that is true for your application (true conditions are denoted by X, and “don’t-care” conditions by –).

Removing Fortran Conflicting References

For each object or executable program that contains conflicting references that you want resolved to Fortran routines, you must replace the conflicting names with names that are unambiguous, as shown in the examples in this section. Under MVS, you will use the cataloged procedure AFHWN, or under TSO/E, a CLIST, in conjunction with data set SCEESAMP(AFHWNCH) to effect the name replacement. (For information about cataloged procedure AFHWN, see “AFHWN — Resolving Name Conflicts between C and Fortran” on page 113.)
You can change one or several modules per step, as you wish. Use one of the following examples, adapting it to your application, as needed.

SCEESAMP(AFHWNCH) must be included immediately preceding each individual executable program whose names are to be changed, as shown in each example. AFHWNCH is a data set containing linkage-editor CHANGE statements to change all conflicting names in the module to which it is applied to names known unambiguously as Fortran routines. For example, CHANGE ABS(A#BS) replaces any reference to ABS, a conflicting name, with a reference to A#BS, the Fortran absolute value routine. A complete list of the conflicting names and their corresponding unambiguous Fortran names can be seen in Table 61 on page 476.

The modules resulting from this process have had all their conflicting names replaced. Having no name conflicts, they can, at any time, be linked as part of one or more executable programs in an application, for example:

- Under MVS, by using one of the CEEW* cataloged procedures discussed in "IBM-Supplied Cataloged Procedures" on page 105.
- Under TSO/E, by using the LINK command as discussed in "Link-editing your application using the LINK command" on page 84.

Note that when a module has had its conflicting references to CLOCK or EXIT changed, it is no longer usable with the VS FORTRAN Version 2 library.

**Changing One Module per Step (MVS):** Under MVS, the example in Figure 5 produces one executable program. Conflicting names in USER.INPUT.LOAD(MEM1) are replaced; USER.RESULT.LOAD(MEM1CHG) is the resulting executable program.

```
//CHGNAM EXEC PROC=AFHWN,PGMLIB=USER.RESULT.LOAD,GONAME=MEM1CHG
//USERINP DD DSNAME=USER.INPUT.LOAD,DISP=SHR
//LKED.SYSIN DD *
   INCLUDE SCEESAMP(AFHWNCH)
   INCLUDE USERINP(MEM1)
/*
```

*Figure 5. Changing Conflicting Names in an Executable Program under MVS*

The example in Figure 6 on page 20 produces several executable programs. Conflicting names in USER.INPUT.LOAD(MEM1, MEM2, and MEM3) are replaced; the resulting executable programs are USER.RESULT.LOAD(MEM1CHG, MEM2CHG, and MEM3CHG).
Changing One Module per Step (TSO/E): Under TSO/E, the example in Figure 7 produces a single executable program. Conflicting names in USER.INPUT.LOAD(MEM1) are replaced; the resulting executable program is USER.RESULT.LOAD(MEM1CHG).

PROC 0

INCLUDE USERINP(MEM3)
/*

Figure 8. Changing Conflicting Names in Several Executable Programs under TSO/E

Changing Multiple Modules per Step (MVS): [Figure 9] shows an example for MVS. Conflicting names in USER.INPUT.LOAD(MEM1, MEM2, and MEM3) are replaced; USER.RESULT.LOAD(MEM1CHG) is the resulting executable program. You must explicitly include AFHWNCH before each individual program.

Figure 9. Changing Conflicting Names in Multiple Executable Programs under MVS

Changing Multiple Modules per Step (TSO/E): [Figure 10 on page 22] contains an example for TSO/E. Conflicting names in USER.INPUT.LOAD(MEM1, MEM2, and MEM3) are replaced; the resulting executable program is USER.RESULT.LOAD(MEM1CHG). You must explicitly link-edit AFHWNCH before each individual executable program.
Relink-editing a Pre-Language Environment Executable Program

The action to take to relink-edit a pre-Language Environment executable program depends on whether it contains a reference to one or more of the conflicting names shown in Table 4 on page 17:

- If the executable program contains no reference to any of the conflicting names, but contains parts that reference Fortran routines not in the list of conflicting names, replace the Fortran routines with the equivalent Language Environment routines by using the module as input to the Fortran library module replacement tool, SCEESAMP(AFHWRLK), which is discussed in “Replacing Fortran Run-Time Library Modules in a Fortran Executable Program” on page 15.
- If the executable program does contain parts that reference one or more of the conflicting names, and the names are to be resolved to Fortran routines, the action you take depends on whether C parts are present in the executable program:
  - If the executable program does not contain any C part that references a conflicting name, replace the Fortran routines with the equivalent Language Environment routines by using the executable program as input to the Fortran library module replacement tool, SCEESAMP(AFHWRLK), and link-edit:
    - Under MVS, by using the AFHWL cataloged procedure (see “AFHWL — Link a Program Written in Fortran” on page 111), as shown in Figure 11.

```
//REPFORT EXEC PROC=AFHWL,PGMLIB=USER.FORT.LOAD
//USERINP DD DSN=USER.FORT.LOAD,DISP=SHR
//LKED.SYSIN DD *
  INCLUDE SCEESAMP(AFHWRLK)
  INCLUDE USERINP(MEM1)
  NAME MEM1(R)
/*
```

- Under TSO/E, by using a CLIST as shown in Figure 12 on page 23. Fortran routines are replaced with the equivalent Language Environment routines using the Fortran library module replacement tool, AFHWRLK. The existing and resulting executable program is USER.FORT.LOAD(MEM1).

```
PROC 0
CONTROL MSG NOFLUSH NOPROMPT SYMLIST CONLIST
LINK ('CEE.SCEESAMP(AFHWNCH)', +
  'USER.INPUT.LOAD(MEM1)', +
  'CEE.SCEESAMP(AFHWNCH)', +
  'USER.INPUT.LOAD(MEM2)', +
  'CEE.SCEESAMP(AFHWNCH)', +
  'USER.INPUT.LOAD(MEM3)', +
LOAD ('USER.RESULT.LOAD(MEM1ING)') +
LIB ('CEE.SAFHFORT', +
  'CEE.SCEELKED') NOTERM LET NCAL
```

Figure 10. Changing Conflicting Names in Multiple Executable Programs under TSO/E
using the Fortran library module replacement tool, AFHWRLK. The existing and resulting executable program is USER.FORT.LOAD(MEM1).

---

```plaintext
PROC 0
CONTROL MSG NOFLUSH NOPROMPT SYMLIST CONLIST
LINK ('CEE.SCEESAMP(AFHWRLK)', +
     'USER.FORT.LOAD(MEM1)', +
     'USER.FORT.LOAD(MEM1)', +
     'CEE.SAFHFORT', +
     'CEE.SCEELKED') NOTERM
```

Figure 12. Replacing Fortran Routines with Language Environment Routines under TSO/E

- If the executable program contains at least one C part that references a conflicting name, you can take one of two possible courses of action depending on whether the individual object modules of the executable program are available to you:
  - If the individual object modules are available, relink-edit the whole application following the name conflict procedure from the beginning to check for possible conflicts, or
  - If the individual object modules are not available, link-edit the executable program:
    - In MVS, using the CEEWL cataloged procedure, as shown in Figure 13 on page 24
    - In TSO/E, using a CLIST, as shown in Figure 14 on page 24

Do the following in the link-edit step, as shown in the following examples:
1. Include the SAFHFORT library Fortran routines to which the conflicting names should resolve.
2. Include the Fortran library module replacement tool, SCEESAMP(AFHWRLK).
3. Do the CSECT replacement necessary to make the C parts of the executable program compatible. There could be CSECTs that you need to replace in addition to those shown in Figure 13 on page 24 or Figure 14 on page 24; see z/OS C/C++ Compiler and Run-Time Migration Guide for the Application Programmer for details.

The following example relink-edits an executable program containing both C and Fortran (or assembler) routines, where C references SQRT, and Fortran references SIN, LOG, and CLOCK. (The language of the main program here is C. If it were Fortran, the ENTRY CEESTART statement would be rewritten to instead name the Fortran main program.) The existing and resulting executable program is USER.FORTC.LOAD(MEM1).
The following example reink-edits an executable program containing both C and Fortran (or assembler) routines, where C references SQRT, and Fortran references SIN, LOG, and CLOCK. The existing and resulting executable program is USER.FORTC.LOAD(MEM1).

```
//FORTC    EXEC PROC=CEEWL,PGMLIB=USER.FORTC.LOAD
//USERINP  DD DSNNAME=USER.FORTC.LOAD,DISP=OLD
//SAFHFORT DD DSNNAME=CEE.SAFHFORT,DISP=SHR
//SCEESAMP DD DSNNAME=CEE.SCEESAMP,DISP=SHR
//LKED.SYSIN DD *
   INCLUDE SAFHFORT(SIN)
   INCLUDE SAFHFORT(LOG)
   INCLUDE SAFHFORT(CLOCK)
   INCLUDE SCEESAMP(AFHWRLK)
   INCLUDE USERINP(MEM1)
   NAME MEM1(R)
   INCLUDE SYSLIB(EDCSTART)
   INCLUDE SYSLIB(CEEROOTB)
   INCLUDE SYSLIB(@@FTOC)
   INCLUDE SYSLIB(@@CTOF)
   INCLUDE USERINP(MEM1)
   ENTRY CEESTART
   NAME MEM1(R)
/*
```

Figure 13. Relink-editing an Executable Program to Resolve Conflicting Names under Batch

```
PROC 0
CONTROL MSG NOFLUSH NOPROMPT SYMLIST CONLIST
  LINK ('CEE.SAFHFORT(SIN)', +
       'CEE.SAFHFORT(LOG)', +
       'CEE.SAFHFORT(CLOCK)', +
       'CEE.SCEESAMP(AFHWRLK)', +
       'USER.FORTC.LOAD(MEM1)') +
  LOAD ('USER.FORTC.LOAD(MEM1)') +
  LIB ('CEE.SCEELKED') NOTERM
  LINK ('CEE.SCEELKED(EDCSTART)', +
       'CEE.SCEELKED(CEEROOTB)', +
       'CEE.SCEELKED(@@FTOC)', +
       'CEE.SCEELKED(@@CTOF)', +
       'USER.FORTC.LOAD(MEM1)') +
  LOAD ('USER.FORTC.LOAD(MEM1)') +
  LIB ('CEE.SCEELKED') NOTERM
/*
```

Figure 14. Relink-editing an Executable Program to Resolve Conflicting Names under TSO/E

PL/I Considerations

This section discusses what you need to know if you link-edit or relink-edit in PL/I.

Link-editing PL/I Subroutines for Later Use

To prelink PL/I subroutines, store them in a load library, and later INCLUDE them with main procedures. The subroutines must be linked with the NCAL link-edit option which causes unresolved external reference error messages from the link-edit process, but these are resolved when the PL/I main procedure is linked with the subroutines. The NCAL option is needed because, in a PL/I load module, all the resident modules must be at the same level. This consistency is ensured because external references are not resolved until the final link.
Preparing to Use Language Environment

Replacing PL/I Library Routines in an OS PL/I Executable Program

Two jobs, IBMWRLK for batch and IBMWRLKC for CICS, located in the sample library SCEESAMP, replace OS PL/I library routines in an OS PL/I executable program with Language Environment routines. For more information about using IBMWRLK or IBMWRLKC, see Enterprise PL/I for z/OS and OS/390 Migration Guide.

Link-Editing Fetchable Executable Programs

The PL/I FETCH and RELEASE statements dynamically load separate executable programs that can be subsequently invoked from the PL/I routine that fetches the executable program. There are some restrictions on the PL/I for MVS & VM statements that can be used in fetched procedures. These are described in PL/I for MVS & VM Language Reference.

Many of those restrictions have been removed with VisualAge PL/I. See VisualAge PL/I Language Reference for the use of FETCH with that compiler.

Fetchable (or dynamically loaded) modules should be link-edited into an executable program library that is subsequently made available for the job step by means of a JOBLIB or STEPLIB DD statement. The FETCH statement can access modules stored in link-pack areas (both the LPA and the ELPA). The search order for modules is defined by z/OS; see “Program Library Definition and Search Order” on page 81 for details.

The step that link-edits a fetchable executable program into a library requires the following linkage editor control statements:

- An ENTRY statement to define the entry point into the PL/I routine.
- A NAME statement to define the name used for the fetchable executable program. This statement is required if the NAME compiler option is not used and if the name is not specified in the DSN parameter in the SYSLMOD DD statement used to define the executable program library.

The name or any alias by which the fetchable executable program is identified in the executable program library must appear in a FETCH or RELEASE statement within the scope of the invoking procedure.

```
//FETCH JOB
//STP      EXEC IEL1CL
//PLI.SYSIN DD *
  :
  PL/I source(fetchable)
  :
/
//LKED.SYSLIN DD *
  ENTRY procedure-name
  INCLUDE OBJMOD
  NAME FETCH1
*/
//LKED.SYSLMOD DD DSN=PRVLIB,...
//LKED.OBJMOD DD DSN=&&LOADSET,DISP=(OLD,...
```

Figure 15. Example of Link-Editing a Fetchable Executable Program

Language Environment-conforming COBOL or C modules can be loaded dynamically by the PL/I FETCH statement. The cataloged procedure IEL1CL
Prefering to Use Language Environment

includes both the compilation and the link-editing of the fetchable PL/I module. For further details on cataloged procedure IEL1CL, see *PL/I for MVS & VM Programming Guide*.

PL/I Link-Time Considerations

The product structure for PL/I has changed from the previous PL/I version. Most JCL and CLISTs that link-edit a PL/I application using the OS PL/I library must be changed. These changes include:

- The OS PL/I multitasking library PLITASK has been replaced by SIBMTASK, which is required to have multitasking support. SIBMTASK must be concatenated before SCEELKED.
  
  Note that VisualAge PL/I does not currently support multitasking. Language Environment continues to support PL/I multitasking for PL/I for MVS & VM as well as previous, supported levels of the PL/I product.

- The PLIBASE and SIBMBASE libraries have been replaced by:
  
  - SCEELKED, which contains resident routines that are linked with the application and are used to resolve external references at link-edit time.
  
  - SIBMMATH, which contains the stubs for old OS PL/I V2R3 math library routines. In link-edit steps, this library must precede SCEELKED if old math results are desired in a particular executable program.
  
  - SIBMCALL, which is required to provide PLICALLA and PLICALLB compatibility if PL/I for MVS & VM applications use OS PL/I PLICALLA or PLICALLB as an entry point. SIBMCALL must be concatenated before SCEELKED.
  
  - SIBMCAL2, which is very similar to SIBMCALL, but is only used with VisualAge PL/I.

  **Note:** SCEELKED and SIBMCAL2 are the only libraries that apply for VisualAge PL/I.

Fetching Modules with Different AMODEs

Language Environment supports the PL/I FETCH/RELEASE facility. No special considerations apply to this support when both the fetching executable program and the fetched executable programs have the AMODE(ANY) attribute or both have the AMODE(24) attribute.

Language Environment also supports the fetching of a load module that has a different AMODE attribute than the executable program issuing the FETCH statement. Language Environment performs the AMODE switches in this case, and the following constraints apply:

- If any fetched module is to execute in 24-bit addressing mode, the fetching module must be loaded into storage below 16M, and must have the RMODE(24) attribute regardless of its AMODE attribute.

- Any variables passed as parameters to a fetched routine must be addressable in the AMODE of the fetched procedure. For any fetched executable program that is to be executed in 24-bit addressing mode, you must ensure that:
  
  - If any parameter resides in a HEAP area, the BELOW suboption of the HEAP option is specified.
  
  - If any parameter resides in STATIC storage of the fetching executable program, the fetching executable program has the RMODE(24) attribute so that its STATIC storage is below 16M.
If any parameter resides in AUTOMATIC storage, no special considerations apply because ALL31(OFF) and STACK(,,BELOW) run-time options have been used. If the two constraints described above cause problems, then you can copy the variable to a like variable with the AUTOMATIC attribute and pass the copy to the fetched AMODE(24) procedure, with the BELOW suboption of the HEAP option specified.

- PL/I object modules can be link-edited into overlay executable programs and run as overlay executable programs. Such programs have the attributes AMODE(24) and RMODE(24).

When a PL/I routine fetches another PL/I procedure, it is possible for a condition to arise in the fetched procedure for which a PL/I ON-unit was established in the fetching procedure.

PL/I imposes the restriction that if an ON-unit is established while the current addressing mode is 24-bit, and the condition is raised while the addressing mode is 31-bit, the ON-unit is not invoked. This is because PL/I must invoke the ON-unit in the addressing mode in which it was established. If the ON-unit was established in 24-bit addressing mode but the condition arose in 31-bit addressing mode, the code and data required to process the error might not even be addressable in 24-bit addressing mode.
Chapter 3. Using Extra Performance Linkage (XPLINK)

What is XPLINK?

Extra Performance Linkage (XPLINK) is a new call linkage between programs that has the potential for a significant performance increase when used in an environment of frequent calls between small functions or subprograms.

Objectives

The C/C++ subroutine linkage on z/OS cannot be considered state-of-the-art with respect to performance. It represents a disproportionate percentage of total execution time, higher yet for C++ than for C due to the many, typically small, functions. Depending on the style of programming, the total prolog/epilog cost may reach a double digit percentage even for C, and thus represents a significant potential for further program optimization.

The objective of XPLINK is to significantly speed up the linkage for C and C++ routines by using a downward-growing stack and by passing parameters in registers. It includes support for reentrant and non-reentrant code, for calls to functions in DLLs, and compatibility with old code.

With XPLINK, the linkage and parameter passing mechanisms for C and C++ are identical. If you link to a C function from a C++ program, you should still specify extern C to avoid name mangling.

The primary objective of XPLINK is to make subroutine calls as fast and efficient as possible by removing all nonessential instructions from the main path.

This is achieved by introducing the following:

• Stack growth from higher to lower addresses ("negative-" or "downward-growing"):
  – to eliminate overhead in stack frame allocation
  – to eliminate the need to check for inline stack overflow
  – to allow an improved epilog
  – to allow addressability to information (such as parameters) in the caller’s stack frame

• Biasing the stack pointer (by 2048 bytes), so that small functions can save registers in their own stack frame before updating the stack pointer, avoiding address generation interlocks.

• Reassignment of registers (see "XPLINK Register conventions" on page 35) to support more efficient saving and restoring of registers in function prologs and epilogs.

• Parameter passing in registers and accepting return values in registers.

• Elimination of Interlanguage Call (ILC) overhead (marking of stack frame) for non-ILC calls.

• Faster call sequences for inter-module calls.

• Passing the address of the data area associated with a function, its "environment," to the function on entry.

• No branching around Language Environment words.

• Use of relative branching for function calls where possible.
Using XPLINK

- Unification of the various (RENT and NORENT, DLL and NODLL) function pointer implementations, reducing the costs of all operations involving function pointers.

An important additional objective is the reduction in module size in memory. This is accomplished by eliminating unused information in function blocks.

Support for XPLINK

XPLINK support is available for applications running under the following environments:

- Batch
- TSO/E
- z/OS UNIX

It is not available for applications running under CICS.

XPLINK support is available with the compiler for the following programming language:

- z/OS C and C++

There is limited XPLINK support in the following areas:

- DB2 — EXEC SQL calls are defined using linkage OS which is supported from XPLINK callers.
- IMS — Language Environment provides the CTDLI interface (a ctdli() function call) for C and C++ callers. This interface is defined in the ims.h header as using linkage OS which is supported from XPLINK callers.
- In general, any system service that is defined as using linkage OS is a supported call from an XPLINK program.
  - If it requires OS linkage conventions but not a Language Environment-conforming stack (that is, it only needs a 72-byte save area), then the function can be defined as OS_NOSTACK (the default when #pragma linkage(...,OS) is specified). This option provides the best performance because the compiler generates OS linkage calling conventions directly – no call through glue code is required.
  - If it requires OS linkage conventions and a Language Environment-conforming stack, then the function can be defined as OS_UPSTACK. For this option the compiler will generate a call through Language Environment glue code that will switch to OS linkage conventions and the non-XPLINK upward-growing stack.

For more information, see either z/OS Language Environment Writing Interlanguage Communication Applications or z/OS C/C++ Language Reference.

For additional information, see XPLINK Restrictions" on page 40.

XPLINK Concepts and terms

XPLINK

Extra Performance Linkage (XPLINK) is a new call linkage between programs which has the potential for a significant performance increase when used in an environment of frequent calls between small functions or subprograms.
non-XPLINK application
A non-XPLINK application is one in which none of the executables involved have been compiled with the XPLINK compiler option specified.

XPLINK application
An XPLINK application is one in which at least one of the executables involved as been compiled with the XPLINK compiler option specified. XPLINK and non-XPLINK compiled source code cannot be link-edited together into the same executable, but XPLINK and non-XPLINK executables (for example, DLLs) can be mixed in the same application. Note that the performance advantage from XPLINK is increased as the percentage of XPLINK executables in an application increases.

XPLINK environment
An XPLINK environment is one in which Language Environment has initialized the necessary resources to run an XPLINK application (for example, a downward-growing stack). This is accomplished by either invoking an initial program that has been compiled with the XPLINK compiler option specified, or specifying the XPLINK(ON) run-time option.

downward-growing stack
The standard Language Environment stack is upward-growing. A main feature of XPLINK’s more efficient program prolog code is a program stack which grows from higher to lower addresses. This provides implicit protection against exceeding available stack storage, rather than having to make an explicit test, and therefore reduces path length.

guard page
A write-protected area of storage at the low address end of a downward-growing stack segment. This allows a stack frame (smaller than the size of the guard page) to be allocated simply by storing into the low address of the stack frame. Stack segment overflow and extension is triggered by the exception resulting from a prolog storing into the guard page (implicit stack overflow detection).

glue code
With respect to XPLINK compatibility, glue code refers to the code inserted between XPLINK and non-XPLINK executables, which converts the stack structure, registers and parameter list into a format suitable for the called function, and then restores the environment upon return.

The XPLINK stack
Stack storage is automatically created by Language Environment and is used for routine linkage and automatic storage. This section describes the way the XPLINK stack differs from the standard Language Environment stack, which is described in detail in "Stack storage overview" on page 169.

The prolog of a function usually allocates space (referred to as a "frame", "Stack Frame", or "DSA" - dynamic storage area) in the Language Environment-provided stack segment for its own purposes and to support calls to other routines.

Figure 16 on page 32 shows the structure of the standard Language Environment stack. Note that the DSAs in the standard (upward-growing) Language Environment stack are allocated from lower to higher addresses. Figure 17 on page 32 shows how the XPLINK (downward-growing) stack is different, specifically that the DSAs are allocated from higher to lower addresses, with the presence of the guard page to mark the bottom of the stack.
The XPLINK stack frame layout shows the XPLINK stack frame layout.

The XPLINK stack register (general purpose register (GPR) 4) is "biased," meaning it points to a location 2048 bytes before the stack frame for the currently active routine. It grows from numerically higher storage addresses to numerically lower ones, that is, the stack frame for a called function is normally at a lower address than the calling function. The stack frame is aligned on a 32-byte boundary.
Save area (48 bytes): This area is always present when a stack frame is required. It holds up to 12 registers. The first two words hold, optionally, GPRs 4 and 5, which contain the address of the previous stack frame and the environment address passed into the function. This is followed by the two words containing GPR 6, which may or may not hold the actual entry point address (depending on the type of call), and GPR 7, the return address. GPR 8 through GPR 15, as used by the called function, are saved in the following 32 bytes. Table 7 on page 35 shows the XPLINK register conventions.

Except when registers are saved in the prolog, this area may not be altered by compiled code. The PPA1 GPR Save Mask indicates which GPRs are saved in this area by the prolog.

Stack overflow is detected when the STM instruction stores into the write-protected guard page while trying to save the registers in this save area.

Storage of the Backchain field in the save area is triggered by the optional XPLINK(BACKCHAIN) compiler option (or at the convenience of the compiler). This adds slightly to the cost of the prolog code, but may increase the serviceability characteristics of the application by providing a DSA backchain pointer in the save area. Note that this backchain pointer may or may not be valid, depending on the options specified when a function was compiled.
Using XPLINK

The third slot in the save area contains the value in GPR 6 on entry to the routine. If the routine was called with a BASR instruction, this will be the address of the function’s entry point. The fourth slot contains the return address. The return point can be examined to determine how the function was called: if with a BASR instruction then the entry point address can be found in the third slot of the save area; if with a branch relative instructive, then the entry point can be computed from the return address and the branch offset contained in the branch relative instruction.

Reserved (8 bytes): This area is always present and is for the exclusive use of the run-time environment. It is uninitialized by compiled code.

Argument area prefix (4 bytes): This area is always present and is for the exclusive use of the run-time environment. It is uninitialized by compiled code.

Argument area (minimum 16 bytes): This area (at a fixed DSA offset of 64 bytes into the caller’s stack frame) contains the argument lists which are passed on function calls made by the function associated with this stack frame. The called function finds its parameters in the caller’s stack frame. Note that arguments passed in registers will not be present in the argument area in the save area. This can be overridden by the optional XPLINK(STOREARGS) compiler option. This adds slightly to the cost of the prolog code, but may increase the serviceability characteristics of the application by providing a complete record of the arguments passed as input to a function.

A minimum of 4 words (16 bytes) will always be allocated.

Local storage: This is the space owned by the executing procedure and may be used for its local variables and temporaries.

Total stack frame size: The total stack frame size is calculated by adding all above fields and by rounding the sum up to a quadword boundary.

Stack overflow
To maximize function call performance, XPLINK replaces the explicit inline check for overflow with a storage protect mechanism that detects stores past the end of the stack segment.

The stack floor is the lowest useable address of the current stack segment. Towards lower addresses it is preceded by a store-protected guard page used to detect stack overflows.

Availability of space for a stack frame is ensured in the function prolog usually by storing into the start of the called function’s frame. In case of overflow, this triggers an exception in turn causes a discontiguous extension of the stack by Language Environment. Functions with a DSA larger than the guard page use the stack floor address in the CAA to verify space availability. Allocation and deallocation of extensions is transparent to the application.

To make the stack appear contiguous to the application, a small stack frame containing all fields up to and including the Argument area will be allocated in the new stack segment for use by the called function, and the contents of the caller’s stack, up to the end of the argument area, is copied into the new stack segment. The length of the argument list expected is available in the called function’s PPA1 except for vararg functions, where the entire argument area in the calling function must be copied.
Stores into the guard page done outside the prolog done outside `alloca()` built-in processing should be treated as invalid and cause the application to be terminated.

Stack overflow is detected by the STM instruction that is used to save registers in this save area.

Initial stack segment size and the stack segment increment size are controlled by the STACK run-time option (see [z/OS Language Environment Programming Reference](https://www.ibm.com/support/knowledgecenter/en/a439796/leenvr5r/lnenv_r_option_list.html#lnenv_r_stack_option)).

### XPLINK Register conventions

XPLINK introduces a register scheme which is very different from standard OS linkage, in order to optimize the performance of saving and restoring registers in function prologs and epilogs. The registers which are saved in the register save area of the XPLINK stack frame are described in “Save area (48 bytes)” on page 33.

Table 7 shows the layout of the XPLINK interface.

XPLINK Parameter passing and return code conventions
XPLINK uses a logical argument list consisting of contiguous 32-bit words, where some arguments are passed in registers and some in storage.

The argument list is located in the caller's stack frame at a fixed offset (+2112) from the stack register (GPR 4). It provides space for all arguments, including those passed in registers. It also includes an extra unused word (4 bytes), which may be required in compatibility situations, at the end of the argument area. Its size is sufficient to contain all the arguments passed on any call statement from a procedure associated with the stack frame.

Function return values are also returned in registers. When the return value won't fit in registers, it is always completely returned in a buffer allocated by the caller. For more details on XPLINK parameter and return value conventions, see z/OS Language Environment Vendor Interfaces.

When XPLINK should be used

The type of application that could benefit most from using XPLINK is an application that makes many calls to small functions. C++ is a good example of this, since the OO programming model makes this possible. C applications that make many function calls may also be suitable for XPLINK.

To further enhance the performance of an XPLINK application, the IEEE binary floating-point math library should be used by specifying the FLOAT(IEEE) compiler option. This math library has been recompiled entirely in XPLINK, while the Hexadecimal math library remains non-XPLINK and therefore requires a call through glue code from XPLINK applications.

When XPLINK should not be used

Functions compiled XPLINK and NOXPLINK cannot be combined in the same program object (except when the #pragma linkage(0s) directive is used in C, or extern in C++; see z/OS Language Environment Writing Interlanguage Communication Applications for more information).

While XPLINK can provide a significant performance enhancement to the right kind of application, it can also degrade the performance of an application that is not suitable for XPLINK.

One way to call an XPLINK function from non-XPLINK is to use the DLL call mechanism. But there is an overhead cost associated with calls made from non-XPLINK to XPLINK, and from XPLINK to non-XPLINK. This overhead includes the need to swap from one stack type to another and to convert the passed parameters to the style accepted by the callee. Applications that make a large number of these "cross-linkage" calls may lose any benefit obtained from the parts that have been compiled XPLINK, and in fact performance could be degraded from the pure non-XPLINK case. If the number of pure XPLINK function calls is significantly greater than the number of "cross-linkage" calls, then the cost saved on XPLINK calls will recover some of the costs associated with calls that involve stack swapping.

When you introduce an XPLINK program object into your application, for example an XPLINK version of a vendor-DLL which your application uses, then your application must now run in an XPLINK environment (this is controlled by the XPLINK run-time option). In an XPLINK environment, an XPLINK version of the
C/C++ Run-time Library (RTL) is used. You cannot have both the non-XPLINK and XPLINK versions of the C/C++ RTL active at the same time, so in an XPLINK environment, non-XPLINK callers of the C/C++ RTL will also incur this stack swapping overhead.

The maximum performance improvement can be achieved by recompiling an entire application XPLINK. The further the application gets from pure XPLINK, the less the performance improvement, and at some point you may actually see a performance degradation.

The only compiler that supports the XPLINK compiler option is the z/OS C/C++ compiler. All COBOL and PL/I programs are non-XPLINK, and therefore calls between COBOL or PL/I and XPLINK-compiled C/C++ are cross-linkage calls and will incur the stack swapping overhead. For more information on making ILI calls with XPLINK, refer to z/OS Language Environment Writing Interlanguage Communication Applications.

If the application contains C or C++ and the XPLINK(ON) run-time option is specified, then the XPLINK-compiled version of the C Run-time Library (RTL) is loaded, which will run on the downward-growing stack. When non-XPLINK functions call C RTL functions in this environment, a swap from the upward-growing stack to the downward-growing stack will occur. This results in additional overhead that could cause a performance penalty. Applications that make heavy use of the C RTL from non-XPLINK callers should be aware of this, and if necessary for performance reasons, either run in a pure non-XPLINK environment with XPLINK(OFF) (the default in this case), or convert as much of the application to XPLINK as possible and run with XPLINK(ON).

Applications that use Language Environment environments that are not supported in an XPLINK environment, or that use products that are not supported in an XPLINK environment (for example, CICS), can not be recompiled as XPLINK applications.

How is XPLINK enabled?

XPLINK is enabled on several levels, including a compiler option and several run-time options.

XPLINK Compiler option

The C/C++ XPLINK compiler option produces an object that uses the XPLINK calling conventions. This compiler option is described in detail in z/OS C/C++ User’s Guide.

XPLINK Run-Time Option

Language Environment will initialize the enclave as an XPLINK environment if the initial program is compiled XPLINK or the XPLINK(ON) run-time option is specified. If the initial program is non-XPLINK but may call an XPLINK program later in its execution, then the XPLINK(ON) run-time option is required so that the XPLINK resources will be allocated and available when they are needed.

Applications that consist only of non-XPLINK functions (for example COBOL or PL/I) should not execute with the XPLINK(ON) run-time option, because this option provides no benefit when not running an XPLINK application, and could result in performance degradation. In fact, for non-XPLINK applications, enabling this run-time option could result in abends for applications that have not been tested to
run in an XPLINK environment, for example, if they use resources or subsystems that are restricted in an XPLINK environment. See “XPLINK Restrictions” on page 40.

No AMODE 24 routines are allowed in an enclave that uses XPLINK. When an application is running in an XPLINK environment (that is, either the XPLINK(ON) run-time option was specified, or the initial program was compiled XPLINK), the ALL31 run-time option will be forced to ON. No message will be issued to indicate this action. In this case, if a Language Environment run-time options report is generated using the RPTOPTS run-time option, the ALL31 option will be reported as “Override” under the LAST WHERE SET column.

When an application is running in an XPLINK environment (that is, either the XPLINK(ON) run-time option was specified, or the initial program was compiled XPLINK), the STACK run-time option will be forced to STACK(,,ANY). Only the third suboption of the STACK run-time option is changed by this action, to indicate that stack storage can be allocated anywhere in storage. No message will be issued to indicate this action. In this case, if a Language Environment run-time options report is generated using the RPTOPTS run-time option, the STACK option will be reported as “Override” under the LAST WHERE SET column.

Related run-time options
The STACK run-time option controls the allocation of the thread's stack storage for the standard Language Environment upward growing stack and the XPLINK downward-growing stack. STACK controls storage allocation for the initial thread in a multi-threaded application.

Similarly, the THREADSTACK run-time option controls the allocation of stack storage for the upward and downward-growing stacks, for other than the initial thread in a multi-threaded application. The THREADSTACK run-time option replaces the NONIPTSTACK run-time option. The NONIPTSTACK run-time option remains for compatibility, but it has not been enhanced for XPLINK.

Building and running an XPLINK application

The detailed procedures for building and running non-XPLINK Language Environment-conforming applications can be found in the chapters which follow.

The procedures for building XPLINK Language Environment-conforming applications can be summarized as:

1. Compile the application with an XPLINK compiler (the C/C++ compiler) using the XPLINK compiler option.
2. Link-edit, with the DFSMS binder, the application (specifying a PDSE or HFS file as the output data set) with the object files and the following Language Environment input:
   • Where SYSLIB for non-XPLINK applications usually lists the SCEELKED, SCEELKEX, SCEEOBJ and SCEECPP data sets, the SYSLIB for link-editing an XPLINK application replaces these with the SCEEBND2 data set. SCEEBND2 contains all object files necessary for building Language Environment-conforming XPLINK applications. If you attempt to link-edit an XPLINK application using the non-XPLINK static libraries, or vice versa, you will receive the binder error message IEW2469E indicating a mismatch in linkage type between function reference and definition.
   • If the XPLINK application calls C run-time library (RTL) functions, it must include the XPLINK C RTL side-deck CELHS003 that is in the SCEELIB data
set. This is included automatically by c89 when the -wL,xplink option is specified. See [z/OS UNIX System Services Command Reference](https://www.ibm.com) or [z/OS C/C++ User’s Guide](https://www.ibm.com) for information about building XPLINK applications in batch, TSO/E and z/OS UNIX.

- If the XPLINK application calls Language Environment AWIs or CWIs, it must include the XPLINK Language Environment side-deck CELHS001 that is in the SCEELIB data set.

- If the XPLINK application is written in C++, it picks up Language Environment C++ RTL definitions from the XPLINK C++ side-deck CELHSCPP that is in the SCEELIB data set. This side-deck is used instead of the SCEECPP data set (the SCEECPP data set is used by non-XPLINK applications).

3. Run the application by providing both SCEERUN and SCEERUN2 data sets in the MVS program search order, for example STEPLIB or LNKLIST.

Note that SCEERUN and SCEERUN2 can be specified in any search order. The XPLINK(ON) run-time option is required if the initial program in the application is non-XPLINK and XPLINK programs may be called (via DLL).

**Other considerations**

When you compile and link-edit a program, the resulting executable is either XPLINK or non-XPLINK. That is, XPLINK-compiled parts and NOXPLINK-compiled parts cannot be link-edited together in the same program object. The one exception to this is the use of the #pragma linkage(OS) directive for C (or extern "OS" for C++). The intent here is to allow the calling of existing assembler programs that typically perform some function that cannot be done in C or C++ without having to rewrite the assembler program using XPLINK conventions (although this could be done if performance is critical, see the chapter on “Combining C or C++ and Assembler” in [z/OS C/C++ Programming Guide](https://www.ibm.com)). XPLINK and non-XPLINK executables can be mixed at run time, for example by using DLL function calls. An XPLINK function can call a non-XPLINK function in a separate DLL, and vice versa. If needed, glue code will be inserted automatically by Language Environment to perform the necessary stack switching and parameter passing adjustments.

The existing static/resident libraries cannot be be used when building XPLINK applications. They contain static parts that get resolved by the binder before the entries in the XPLINK side-decks.

The DFSMS binder must be used to create an XPLINK application. The resulting program module exploits the format of the PM3 Program Object.

There are also XPLINK versions of locales and iconv converters which are provided for use by XPLINK applications.

There is a new XPLINK-compiled version of the Curses archive file. It is called libcursesexp.a, and resides in /usr/lib. The usage will be the same as the old archive file except the compiler and environment must be set up using XPLINK. The following is an example of compiling test.c with the new Curses XPLINK archive:

```
c89 -o test -Wc,xplink -Wl,xplink test.c -lcursesexp
```

**XPLINK / non-XPLINK compatibility**

Compatibility with XPLINK only exists for Language Environment-conforming non-XPLINK applications which are able to run AMODE(31).
Using XPLINK

XPLINK Compatibility Support is defined as the ability for programs compiled NOXPLINK (these may be non-XPLINK C or C++ (Fastlink), COBOL, PL/I or OS Linkage Assembler) to transparently call programs that are compiled XPLINK, and vice versa.

This transparent compatibility is provided at the Program Object boundary. It is also provided at the load module boundary, for compatibility with prelinker-built executables. That is, a Program Object (or load module) containing a caller of one linkage type (XPLINK or NOXPLINK) may call a function compiled with the opposite linkage type as long as the called function resides in a different Program Object (or load module). Program Objects can reside in either a PDSE or the HFS; load modules reside in PDSs.

Compatibility requires that the differences between stack structures, register conventions, and parameter lists are handled. Language Environment will automatically insert the glue code which performs the necessary transitions between XPLINK and non-XPLINK functions.

The main call linkage supporting XPLINK Compatibility is the DLL call mechanism, but C's fetch() and Language Environment's CEEFETCH Assembler macro are also supported.

The following are not supported for XPLINK:
- COBOL dynamic call of an XPLINK function
- PL/I FETCH
- CEELOAD

XPLINK Restrictions

- In general, XPLINK-compiled objects cannot be statically bound with non-XPLINK-compiled objects. A program object (or load module) consists of either XPLINK objects or non-XPLINK objects.

  The one exception to this is when an XPLINK function calls a function defined as either OS_UPSTACK or OS_NOSTACK. In this case the called function is non-XPLINK and uses OS linkage conventions. However, since the bind step of XPLINK and non-XPLINK executables uses different data sets (see Planning to Link-Edit and Run on page 8), all external references from the non-XPLINK function must be resolved using the XPLINK link-edit data sets. For example, if a called OS_UPSTACK function makes a call to the C run-time (RTL), the C RTL function must be resolved via the CELHS003 side deck in SCEELIB. It cannot use the SCEELKED static stubs since these are not used to bind XPLINK objects.

  The intent of OS_UPSTACK is to be able to call a non-XPLINK function that is not going to be recompiled or rewritten as XPLINK, but is itself a leaf routine and does not make any further calls. The intent of OS_NOSTACK is to call non-XPLINK functions that only need an OS linkage register save area, and are either leaf routines or make calls to other system services that do not use the Language Environment stack.

  XPLINK Assembler programs cannot resolve the address and environment of other XPLINK functions in order to call them. If a function pointer is passed to an XPLINK Assembler program, it can be used to call that function as long as XPLINK calling conventions are used (see z/OS Language Environment Vendor Interfaces). There is currently no CALL macro support for XPLINK.
The intent of the XPLINK Assembler support is to be able to call an Assembler function that has been rewritten using XPLINK conventions (either for performance reasons or to perform some function not easily implemented in C or C++), but is itself a leaf routine and does not make any further calls.

- Calls between XPLINK and non-XPLINK functions are allowed when they cross program object (or load module) boundaries. The use of DLLs is the primary method, where a function in a non-XPLINK DLL calls another function in an XPLINK DLL (or vice versa). The fetch() function also provides compatibility between XPLINK and non-XPLINK functions.
- The following do not support calls to XPLINK functions:
  - COBOL dynamic call
  - PL/I FETCH
- XPLINK functions can only call non-XPLINK functions that are also Language Environment-conforming, that is, they were compiled using a Language Environment-conforming compiler.
- XPLINK applications must run AMODE 31, so the ALL31 run-time option will be forced ON. This means all non-XPLINK applications that can call or be called by an XPLINK application must also run AMODE 31.
- You should make a reference from XPLINK code into non-XPLINK code only if the reference is by an imported function or variable, or the function pointer is a parameter into the XPLINK code. This prevents incompatible references to a non-XPLINK function entry point. If the non-XPLINK code exposes a function entry point directly to the XPLINK code (as a global variable, as part of a structure that is passed as a parameter, or by passing an explicit return value), the XPLINK code will not be able to correctly use it.
- XPLINK applications must be built using the DFSMS Binder, and they must reside in either a PDSE or the HFS. The Prelinker cannot be used to create an XPLINK application.
- The following environments and subsystems do not support applications that have been compiled XPLINK:
  - CICS (Chapter 27)
  - DB2 stored procedures cannot be compiled XPLINK (Chapter 28)
  - A nested (child) enclave must run with the same XPLINK environment as its parent (Chapter 33)
  - The CEEBXITA and CEEBINT user exits cannot be XPLINK (Chapter 30)
  - PICI
  - LRR (Chapter 31, Section 4)
  - System Programmer C (SPC)
  - C Multitasking Facility (C MTF)
  - PL/I Multitasking
  - DCE
Using XPLINK
Chapter 4. Building and Using Dynamic Link Libraries (DLLs)

The z/OS dynamic link library (DLL) facility provides a mechanism for packaging programs and data into load modules (DLLs) that may be accessed from other separate load modules. A DLL can export symbols representing routines that may be called from outside the DLL, and can import symbols representing routines or data or both in other DLLs, avoiding the need to link the target routines into the same load module as the referencing routine. When an application references a separate DLL for the first time, it is automatically loaded into memory by the system.

There are two types of DLLs: simple and complex. A simple DLL contains only DLL code in which special code sequences are generated by the compiler for referencing functions and external variables, and using function pointers. With these code sequences, a DLL application can reference imported functions and imported variables from a DLL as easily as it can non-imported ones.

A complex DLL contains mixed code, that is, some DLL code and some non-DLL code. A typical complex DLL might contain some C++ code, which is always DLL code, and some C object modules compiled with the NODLL compiler option bound together.

This chapter defines DLL concepts and shows how to build simple DLLs and DLL Applications.

Support for DLLs

DLL support is available for applications running under the following systems:

- z/OS Batch
- CICS
- IMS
- TSO
- z/OS UNIX

It is not available for applications running under SP C, CSP or MTF.

Note: For CICS, all potential DLL executable modules are registered in the CICS PPT control table in the CICS environment and are invoked at run time.

DLL support is available with the compilers for the following programming languages:

- C and C++
- Enterprise COBOL for z/OS and OS/390
- COBOL for OS/390 & VM
- VisualAge PL/I for OS/390
- High Level Assembler (HLASM) Release 5
Dynamic Link Libraries (DLLs)

DLL Concepts and Terms

Function
In this chapter, function is used to generically refer to a callable routine or program, and is specifically applicable to C and C++. In COBOL a function would be a COBOL program or method. In VisualAge PL/I a function would be a PL/I procedure.

Variable
In this chapter, variable is used to generically refer to a data item, such as a static variable in C/C++.

Application
All the code executed from the time an executable program module is invoked until that program, and any programs it directly or indirectly calls, is terminated.

DLL
An executable module that exports functions, variable definitions, or both, to other DLLs or DLL applications. The executable code and data are bound to the program at run time. The code and data in a DLL can be shared by several DLL applications simultaneously. It is important to note that compiling code with the DLL option does not mean that the produced executable will be a DLL. To create a DLL, you must compile with the DLL option and export one or more symbols.

DLL application
An application that references imported functions, imported variables, or both, from other DLLs.

DLL code
DLL code is code that is compiled with the DLL option of the C and COBOL compilers, or any code compiled with the C++ and VisualAge PL/I compilers. Non-DLL code is compiled without the DLL option.

Executable program (or executable module)
A file which can be loaded and executed on the computer. z/OS supports two types:

Load module
An executable residing in a PDS.

Program object
An executable residing in a PDSE or in the HFS.

Object code (or object module)
A file output from a compiler after processing a source code module, which can subsequently be used to build an executable program module.

Source code (or source module)
A file containing a program written in a programming language.

Imported functions and variables
Functions and variables that are not defined in the executable module where the reference is made, but are defined in a referenced DLL.

Non-imported functions and variables
Functions and variables that are defined in the same executable module where a reference to them is made.

Exported functions or variables
Functions or variables that are defined in one executable module and can be referenced from another executable module. When an exported function
or variable is referenced within the executable module that defines it, the exported function or variable is also nonimported.

**Writable Static Area (WSA)**
An area of memory that is modifiable during program execution. Typically, this area contains global variables and function and variable descriptors for DLLs.

**Function descriptor**
An internal control block containing information needed by compiled code to call a function.

**Variable descriptor**
An internal control block containing information about the variable needed by compiled code.

---

### Loading a DLL

A DLL is loaded implicitly when an application references an imported variable or calls an imported function. DLLs can be explicitly loaded by calling `d11load()` or `d1open()`. Due to optimizations performed, the DLL implicit load point may be moved and is only done before the actual reference occurs.

### Loading a DLL Implicitly

When an application uses functions or variables defined in a DLL, the compiled code loads the DLL. This implicit load is transparent to the application. The load establishes the required references to functions and variables in the DLL by updating the control information contained in function and variable descriptors.

If a C++ DLL contains static classes, their constructors are run when the DLL is loaded, typically before the main function runs. Their destructors run once after the main function returns.

To implicitly load a DLL from C or C++, do one of the following:
- Statically initialize a variable pointer to the address of an exported DLL variable.
- Reference a function pointer that points to an exported function.
- Call an exported function.
- Reference (use, modify, or take the address of) an exported variable.
- Call through a function pointer that points to an exported function.

To implicitly load a DLL from COBOL, do one of the following:
- Call a function that is exported from the DLL.
- Set a COBOL procedure-pointer to a function that is exported from the DLL.
- Invoke a method that is defined in a class contained in the DLL.

When the first reference to a DLL is from static initialization of a C or C++ variable pointer, the DLL is loaded before the main function is invoked. Any C++ constructors are run before the main function is invoked.

### Loading a DLL Explicitly

The use of DLLs can also be explicitly controlled by C/C++ application code at the source level. The application uses explicit source-level calls to one or more run-time services to connect the reference to the definition. The connections for the reference and the definition are made at run-time.
Dynamic Link Libraries (DLLs)

The DLL application writer can explicitly call the following C run-time services:
- `d11load()`, which loads the DLL and returns a handle to be used in future references to this DLL
- `dl1queryfn()`, which obtains a pointer to a DLL function
- `dl1queryvar()`, which obtains a pointer to a DLL variable
- `dl1free()`, which frees a DLL loaded with `d11load()`

The following run-time services are also available as part of the Single UNIX Specification, Version 3:
- `d11open()`, which loads the DLL and returns a handle to be used in future references to this DLL
- `dl1close()`, which frees a DLL that was loaded with `d11open()`
- `d11sym()`, which obtains a pointer to an exported function or exported variable
- `d11error()`, which returns information about the last DLL failure on this thread that occurred in one of the `d11open()` family of functions

While you can use both families of explicit DLL services in a single application, you cannot mix usage across those families. So a handle returned by `d11load()` can only be used with `dl1queryfn()`, `dl1queryvar()`, or `dl1free()`. And a handle returned by `d11open()` can only be used with `d11sym()` and `dl1close()`.

Since the `d11open()` family of functions are part of the Single UNIX Specification, Version 3, they should be used in new applications if cross-platform portability is a concern.

For more information about the C run-time services, see [z/OS C/C++ Run-Time Library Reference](z/OS C/C++ Run-Time Library Reference).

To explicitly call a DLL in your application:
- Determine the names of the exported functions and variables that you want to use. You can get this information from the DLL provider's documentation or by looking at the definition side-deck file that came with the DLL. A definition side-deck is a directive file that contains an `IMPORT` control statement for each function and variable exported by that DLL.
- If you are using the `d11load()` family of functions, include the DLL header file `<d11.h>` in your application. If you are using the `d11open()` family of functions, include the DLL header file `<dlfcn.h>` in your application.
- Compile your source as usual.
- Bind your object with the binder using the same AMODE value as the DLL.

Note: You do not need to bind with the definition side-deck if you are calling the DLL explicitly with the run-time services, since there are no references from the source code to function or variable names in the DLL for the binder to resolve. Therefore the DLL will not be loaded until you explicitly load it with the `d11load()` or `d11open()` run-time service.

Figure 19 on page 47, Figure 20 on page 49, and Figure 21 on page 51 are examples of applications that use explicit DLL calls.

**Explicit Use of a DLL in a C Application**

The following example shows explicit use of a DLL in a C application.
#include <dll.h>
#include <stdio.h>
#include <string.h>

#ifdef __cplusplus
    extern "C" {
#endif

typedef int (DLL_FN)(void);
#ifdef __cplusplus
}
#endif

#define FUNCTION "FUNCTION"
#define VARIABLE "VARIABLE"

static void Syntax(const char* progName) {
    fprintf(stderr, "Syntax: %s <DLL-name> <type> <identifier>
    " where
    " <DLL-name> is the DLL to load,
    " <type> can be one of FUNCTION or VARIABLE
    " and <identifier> is the function or variable
    " to reference", progName);
    return;
}

main(int argc, char* argv[]) {
    int value;
    int* varPtr;
    char* dll;
    char* type;
    char* id;
    dllhandle* dllHandle;

    if (argc != 4) {
        Syntax(argv[0]);
        return(4);
    }

Figure 19. Explicit use of a DLL in an application using the dllload() family of functions (Part 1 of 2)
dll = argv[1];
type = argv[2];
id = argv[3];

dllHandle = dllload(dll);
if (dllHandle == NULL) {
    perror("DLL-Load");
    fprintf(stderr, "Load of DLL %s failed\n", dll);
    return(8);
}

if (strcmp(type, FUNCTION)) {
    if (strcmp(type, VARIABLE)) {
        fprintf(stderr, "Type specified was not " FUNCTION " or " VARIABLE \
"\n"); Syntax(argv[0]);
        return(8);
    }

    /*
     * variable request, so get address of variable
     */
    varPtr = (int*)(dllqueryvar(dllHandle, id));
    if (varPtr == NULL) {
        perror("DLL-Query-Var");
        fprintf(stderr, "Variable %s not exported from %s\n", id, dll);
        return(8);
    }
    value = *varPtr;
    printf("Variable %s has a value of %d\n", id, value);
}
else {
    /*
     * function request, so get function descriptor and call it
     */
    DLL_FN* fn = (DLL_FN*) dllqueryfn(dllHandle, id);
    if (fn == NULL) {
        perror("DLL-Query-Fn");
        fprintf(stderr, "Function %s() not exported from %s\n", id, dll);
        return(8);
    }
    value = fn();
    printf("Result of call to %s() is %d\n", id, value);
}
dllfree(dllHandle);

return(0);

---

Figure 19. Explicit use of a DLL in an application using the dllload() family of functions (Part 2 of 2)
```c
#define _UNIX03_SOURCE
#include <dlfcn.h>
#include <stdio.h>
#include <string.h>

#ifdef __cplusplus
extern "C" {
#endif

typedef int (DLL_FN)(void);

#ifdef __cplusplus
}
#endif

#define FUNCTION "FUNCTION"
#define VARIABLE "VARIABLE"

static void Syntax(const char* progName) {
    fprintf(stderr, "Syntax: %s <DLL-name> <type> <identifier>
" " where
" " <DLL-name> is the DLL to open,
" " <type> can be one of FUNCTION or VARIABLE,
" " and <identifier> is the symbol to reference
" " (either a function or variable, as determined by"
" " <type>)\n", progName);
    return;
}

main(int argc, char* argv[]) {
    int value;
    void* symPtr;
    char* dll;
    char* type;
    char* id;
    void* dllHandle;
    if (argc != 4) {
        Syntax(argv[0]);
        return(4);
    }
}
```

Figure 20. Explicit use of a DLL in an application using the dlopen() family of functions (Part 1 of 2)
Explicit Use of a DLL in a COBOL/C Application
The following example shows explicit use of a DLL in a COBOL/C application.

dll = argv[1];
type = argv[2];
id = argv[3];

dllHandle = dlopen(dll, 0);
if (dllHandle == NULL) {
    fprintf(stderr, "dlopen() of DLL %s failed: %s\n", dll, dlerror());
    return(8);
}

/*
* get address of symbol (may be either function or variable)
*/
symPtr = (int*)(dlsym(dllHandle, id));
if (symPtr == NULL) {
    fprintf(stderr, "dlsym() error: symbol %s not exported from %s: %s\n",
                                id, dll, dlerror());
    return(8);
}

if (strcmp(type, FUNCTION)) {
    if (strcmp(type, VARIABLE)) {
        fprintf(stderr, "Type specified was not " FUNCTION " or " VARIABLE "\n");
        Syntax(argv[0]);
        return(8);
    }
    /*
    * variable request, so display its value
    */
    value = *(int *)symPtr;
    printf("Variable %s has a value of %d\n", id, value);
} else {
    /*
    * function request, so call it and display its return value
    */
    value = ((DLL_FN *)symPtr)();
    printf("Result of call to %s() is %d\n", id, value);
}

dlclose(dllHandle);
return(0);

Figure 21. Explicit Use of a DLL in a COBOL/C Application (Part 1 of 2)
Managing the Use of DLLs When Running DLL Applications

This section describes how Language Environment manages loading, sharing and freeing DLLs when you run a DLL application.

Loading DLLs

When you load a DLL for the first time, either implicitly or via an explicit `d11load()` or `dlopen()`, writable static is initialized. If the DLL is written in C++ and contains static objects, then their constructors are run.

You can load DLLs from a z/OS UNIX HFS as well as from conventional data sets. The following list specifies the order of a search for unambiguous and ambiguous file names.

- **Unambiguous file names**
  - If the file has an unambiguous HFS name (it starts with a ./ or contains a /), the file is searched for only in the HFS.
  - If the file has an unambiguous MVS name, and starts with two slashes (/), the file is only searched for in MVS.

```c
#include <stdio.h>
#include <dll.h>
#pragma linkage (AICCDLGT,COBOL)

typedef struct dll_lm {
    char    dll_loadmod_name[12];
    char    dll_func_name[160];
    void (*fptr) (void); /* function pointer */
} dll_lm;

void AICCDLGT (dll_lm *dll, int *rc)
{
    dllhandle *handle;
    void (*fptr1)(void);
    *rc = 0;
    /* Load the DLL */
    handle = dllload(dll->dll_loadmod_name);
    if (handle == NULL) {
        perror("AICCDLGT failed on call to load DLL.\n");
        *rc = 1;
        return;
    }
    /* Get the address of the function */
    fptr1 = (void (*)(void)) dllqueryfn(handle,dll->dll_func_name);
    if (fptr1 == NULL) {
        perror("AICCDLGT failed on retrieving function.\n");
        *rc = 2;
        return;
    }
    /* Return the function pointer */
    dll->fptr = fptr1;
    return;
}
```

Figure 21. Explicit Use of a DLL in a COBOL/C Application (Part 2 of 2)
• **Ambiguous file names**

For ambiguous cases, the settings for POSIX are checked.

- When specifying the POSIX(ON) run-time option, the run-time library attempts to load the DLL as follows:
  1. An attempt is made to load the DLL from the HFS. This is done using the system service BPX1LOD. For more information on this service, see [z/OS UNIX System Services Programming: Assembler Callable Services Reference](http://www.ibm.com/support/docview.wss?rs=125&context=SSS011&ssos=mgmt&_locale=en&uid=swg21687787).

    If the environment variable LIBPATH is set, each directory listed will be searched for the DLL. Otherwise the current directory will be searched for the DLL. Note that a search for the DLL in the HFS is case-sensitive.

    2. If the DLL is found and contains an external link name of eight characters or less, the uppercase external link name is used to attempt a LOAD from the caller's MVS load library search order. If the DLL is not found or the external link name is more than eight characters, then the load fails.

    3. If the DLL is found and its sticky bit is on, any suffix is stripped off. Next, the name is converted to uppercase, and the base DLL name is used to attempt a LOAD from the caller's MVS load library search order. If the DLL is not found or the base DLL name is more than eight characters, the version of the DLL in the HFS is loaded.

    4. If the DLL is found and does not fall into one of the previous two cases, a load from the HFS is attempted.

If the DLL could not be loaded from the HFS because the file was not found or the application doesn't have sufficient authority to search for or read that file (that is, BPX1LOD fails with errno ENOENT, ENOSYS, or EACCESS), then an attempt is made to load the DLL from the caller's MVS load library search order. For all other failures from BPX1LOD, the load of the DLL is terminated. For an implicit DLL load, the error is reported with the errno and errmsg displayed in message CEE3512S. For an explicit DLL load, the d11load() service returns with the failing errno and errmsg values set. Correct the indicated error and re-run the application.

If the DLL could not be loaded from the HFS, an attempt is made to load the DLL from the caller's MVS load library search order. This is done by calling the LOAD service with the DLL name, which must be eight characters or less (it will be converted to uppercase). LOAD searches for it in the following sequence:

  1. Run-time library services (if active)
  2. Job pack area (JPA)
  3. TASKLIB
  4. STEPLIB or JOBLIB. If both are allocated, the system searches STEPLIB and ignores JOBLIB.
  5. LPA
  6. Libraries in the linklist

For more information, see [z/OS MVS Initialization and Tuning Guide](http://www.ibm.com/support/docview.wss?rs=125&context=SSS011&ssos=mgmt&locale=en&uid=swg21687787).

- When POSIX(OFF) is specified the sequence is reversed.
  - An attempt to load the DLL is made from the caller’s MVS load library search order.
  - If the DLL could not be loaded from the caller’s MVS load library then an attempt is made to load the DLL from the HFS.
Dynamic Link Libraries (DLLs)

**Recommendation:** All DLLs used by an application should be referred to by unique names, whether ambiguous or not. Using multiple names for the same DLL (for example, aliases or symlinks) may result in a decrease in DLL load performance. The use of HFS symbolic links by themselves will not degrade performance, as long as the application refers to the DLL solely through the symbolic link name. To help ensure this, when building an application with implicit DLL references always use the same side deck for each DLL. Also, make sure that explicit DLL references with `d11load()` specify the same DLL name (case matters for HFS loads).

Changing the search order for DLLs while the application is running (for example, changing LIBPATH) may result in errors if ambiguous file names are used.

**Sharing DLLs**

DLLs are shared at the enclave level (as defined by Language Environment). A referenced DLL is loaded only once per enclave and only one copy of the writable static is created or maintained per DLL per enclave. Thus, one copy of a DLL serves all modules in an enclave regardless of whether the DLL is loaded implicitly or explicitly. A copy is implicit through a reference to a function or variable. A copy is explicit through a DLL load. You can access the same DLL within an enclave both implicitly and by explicit run-time services.

All accesses to a variable in a DLL in an enclave refer to the single copy of that variable. All accesses to a function in a DLL in an enclave refer to the single copy of that function.

Although only one copy of a DLL is maintained per enclave, multiple logical loads are counted and used to determine when the DLL can be deleted. For a given DLL in a given enclave, there is one logical load for each explicit `d11load()` or `d1open()` request. DLLs that are referenced implicitly may be logically loaded at application initialization time if the application references any data exported by the DLL, or the logical load may occur during the first implicit call to a function exported by the DLL.

DLLs are not shared in a nested enclave environment. Only the enclave that loaded the DLL can access functions and variables.

**Freeing DLLs**

You can free explicitly loaded DLLs with a `d11free()` or `d1close()` request. This request is optional because the DLLs are automatically deleted by the run-time library when the enclave is terminated.

Implicitly loaded DLLs cannot be deleted from the DLL application code. They are deleted by the run-time library at enclave termination. Therefore, if a DLL has been both explicitly and implicitly loaded, the DLL can only be deleted by the run-time when the enclave is terminated.

**Creating a DLL or a DLL Application**

Building a DLL or a DLL application is similar to creating a C, C++, COBOL or VisualAge PL/I application. It involves the following steps:

1. Writing your source code
2. Compiling your source code
3. Binding your object modules
Building a Simple DLL

This section shows how to build a simple DLL. See “Building a Simple DLL Application” on page 60 for information about building a simple DLL application.

Writing DLL Code

Writing Your C DLL Code
To build a simple C DLL, write code using the #pragma export directive to export specific external functions and variables as shown in Figure 22.

```c
#pragma export(bopen)
#pragma export(bclose)
#pragma export(bread)
#pragma export(bwrite)
int bopen(const char* file, const char* mode) {
    ...
} int bclose(int) {
    ...
} int bread(int bytes) {
    ...
} int bwrite(int bytes) {
    ...
} #pragma export(berror)
int berror;
char buffer[1024];
...
```

Figure 22. Using #pragma export to Create a DLL Executable Module Named BASICIO

For the previous example, the functions bopen(), bclose(), bread(), and bwrite() are exported; the variable berror is exported; and the variable buffer is not exported.

Note: To export all defined functions and variables with external linkage in the compilation unit to the users of the DLL, compile with the EXPORTALL compile option. All defined functions and variables with external linkage will be accessible from this DLL and by all users of this DLL. However, exporting all functions and variables has a performance penalty, especially when compiling with the C/C++ IPA option. When you use EXPORTALL you do not need to include #pragma export in your code.

Writing Your C++ DLL Code
To create a simple C++ DLL:

- Ensure that classes and class members are exported correctly, especially if they use templates.
- Use _Export or the #pragma export directive to export specific functions and variables.
Dynamic Link Libraries (DLLs)

For example, to create a DLL executable module TRIANGLE, export the getarea() function, the getperim() function, the static member objectCount and the static constructor for class triangle using #pragma export:

```c
class triangle : public area
{
  public:
    static int objectCount;
    getarea();
    getperim();
    triangle::triangle(void);
};
#pragma export(triangle::objectCount)
#pragma export(triangle::getarea())
#pragma export(triangle::getperim())
#pragma export(triangle::triangle(void))
```

Figure 23. Using #pragma Export to Create a DLL Executable Module TRIANGLE

- Do not inline the function if you apply the _Export keyword to the function declaration.

```c
class triangle : public area
{
  public:
    static int _Export objectCount;
    double _Export getarea();
    double _Export getperim();
    _Export triangle::triangle(void);
};
```

Figure 24. Using _export to Create DLL Executable Module TRIANGLE

- Always export static constructors and destructors when using the _Export keyword.
- Apply the _Export keyword to a class. This keyword automatically exports static members and defined functions of that class, constructors, and destructors.

```c
_class Export triangle
{
  public:
    static int objectCount;
    double getarea();
    double getperim();
    triangle::triangle(void);
};
```

- To export all external functions and variables in the compilation unit to the users of this DLL, you can also use the compiler option EXPORTALL. This compiler option is described in z/OS C/C++ User's Guide and #pragma export directives are described in detail in z/OS C/C++ Language Reference. If you use the EXPORTALL option, you do not need to include #pragma export or _Export in your code.

Writing your COBOL DLL Code
There are no special DLL conditions for writing your COBOL code.
Writing your VisualAge PL/I DLL Code
Any PL/I routine other than an OPTIONS(MAIN) routine can go into a DLL. All
external variables will be exported except those that have the RESERVED attribute.
The latter are exported only if named in the RESERVES clause of a PACKAGE
statement.

Writing Your Language Environment-conforming Assembler DLL Code
To build a simple assembler DLL, your assembler routine must conform to
Language Environment conventions. To do this, begin by using the Language
Environment macros CEEENTRY and CEETERM. The EXPORT= keyword
parameter on the CEEENTRY macro allows you to identify specific assembler entry
points for export. The CEEPDDA macro allows you to define data in your assembler
routine that can be exported. Details on all Language Environment assembler
macros are in "Assembler Macros" on page 483.

Figure 25 on page 58 shows how to use Language Environment macros to create
an Assembler DLL. The CEEENTRY prolog macro has EXPORT=YES specified to
mark this entry point exported. In this particular case we want the exported function
known externally in lower case, so the CEEENTRY is followed by an assembler
ALIAS statement. The ALIAS can be used to "name" the exported function with a
mixed-case name up to 256 characters long. This assembler DLL also has two
exported variables, "DllVar" (initial value = 123) and "DllStr" (initial value is the C
string "Hello World"). When the exported function "dllfunc" is called, it sets "DllVar"
to 456 and truncates the "DllStr" C string to "Hello".
Compiling Your DLL Code

For C source, compile with the DLL compiler option. When you specify the DLL compiler option, the compiler generates special code when calling functions and referencing external variables. Even if a simple application or DLL does not reference any imported functions or imported variables from other DLLs, you should specify the DLL compiler option. Compiling an application or DLL as DLL code eliminates the potential compatibility problems that may occur when binding DLL code with non-DLL code.

Compiling your C source with the XPLINK compiler option will automatic generate DLL-enabled code, so in this case the DLL compiler option is not necessary.

For C++ source, compile as you would any C++ program.

For COBOL source code that defines DLLs, compile with the RENT, DLL and EXPORTALL compiler options. For source code that only references DLLs, compile with the RENT, DLL, and NOEXPORTALL compiler options.
Dynamic Link Libraries (DLLs)

For VisualAge PL/I source, compile as you would any VisualAge PL/I program.

For Assembler source, you must use the GOFF option.

**Note:** DLLs must be reentrant; you should use the RENT C compiler option (C++ and VisualAge PL/I are always reentrant).

**Binding Your DLL Code**

Use the DLL support in the DFSMS binder, rather than the linkage editor, for linking DLL applications. Note that binder-based DLLs must reside in PDSEs, rather than PDS data sets. If a DLL must reside in a PDS load library, the application must be prelinked with the Language Environment prelinker prior to standard linkage editing. See Appendix A, “Prelinking an Application,” on page 569 for further details. When binding a DLL application using the DFSMS binder, the following binder externals are used:

- The binder option CASE(MIXED) is required when binding DLLs that use mixed-case exported names.
- The binder options RENT, DYNAM(DLL), and COMPAT(PM3) or COMPAT(CURRENT) are required.
- When binding a DLL, a SYSDEFSD DD statement must be specified, indicating the data set where the binder should create a DLL definition side-deck. The DLL definition side-deck contains IMPORT control statements for each of the symbols exported by a DLL. If you are using z/OS UNIX, specify the following option for the bind step for c89 or the c++ command:
  
  ```
  -W 1,DLL
  ```

  If the code in the DLL was compiled with the XPLINK compiler option, specify:

  ```
  -W 1,DLL,XPLINK
  ```

- The binder SYSLIN input, the binding code that references DLL code, must include the DLL definition side-decks for the DLLs that are to be dynamically referenced from the module being bound. See z/OS DFSMS Program Management for further details.

**Binding C**

When binding the C object module as shown in Figure 22 on page 55, the binder generates the following definition side-deck:

```
IMPORT CODE 'BASICIO', bopen
IMPORT CODE 'BASICIO', bclose
IMPORT CODE 'BASICIO', bread
IMPORT CODE 'BASICIO', bwrite
IMPORT DATA 'BASICIO', berror
```

You can edit the definition side-deck to remove any functions or variables that you do not want to export. For instance, in the above example, if you do not want to expose berror, remove the control statement IMPORT DATA 'BASICIO', berror from the definition side-deck.

**Notes:**

1. You should also provide a header file containing the prototypes for exported functions and external variable declarations for exported variables.
2. Side-decks are created without newline characters, therefore you cannot edit them with an editor that expects newline characters, such as vi in z/OS UNIX.

For more information on binding C, see z/OS C/C++ User's Guide.
Dynamic Link Libraries (DLLs)

Binding C++
When binding the C++ object modules shown in Figure 23 on page 56, the binder generates the following definition side-deck.

```
IMPORT CODE,TRIANGLE, getarea__8triangleFv
IMPORT CODE,TRIANGLE, getperim__8triangleFv
IMPORT CODE,TRIANGLE, __ct__8triangleFv
```

You can edit the definition side-deck to remove any functions and variables that you do not want to export. In the above example, if you do not want to expose getperim(), remove the control statement IMPORT CODE ,TRIANGLE, getperim__8triangleFv from the definition side-deck.

Notes:
1. Removing functions and variables from the definition side-deck does not minimize the performance impact caused by specifying the EXPORTALL compiler option.
2. Side-decks are created without newline characters, therefore you cannot edit them with an editor that expects newline characters, such as vi in z/OS UNIX.

The definition side-deck contains mangled names, such as getarea__8triangleFv. To find the original function or variable name in your source module, review the compiler listing created or use the CXXFILT utility. This will permit you to see both the mangled and demangled names. For more information on the CXXFILT utility, and on binding C++, see z/OS C/C++ User's Guide

Binding COBOL
When binding a module that contains COBOL programs compiled with the DLL and EXPORTALL compiler options, the binder generates a definition side-deck. If there are programs in the module that you do not want to make available with DLL linkage, you can edit the definition side-deck to remove programs that you do not want to export.

Binding VisualAge PL/I
The considerations for binding VisualAge PL/I are the same as for binding C++ above.

Binding Assembler
When binding the Assembler object module as shown in Figure 25 on page 58, the binder generates the following definition side-deck:

```
IMPORT CODE,'ADLLBEV2','dllfunc'
IMPORT DATA,'ADLLBEV2','D11Str'
IMPORT DATA,'ADLLBEV2','D11Var'
```

The Assembler DLL support requires use of the binder.

Building a Simple DLL Application
A simple DLL application contains object modules that are made up of only DLL-code. The application may consist of multiple source modules. Some of the source modules may contain references to imported functions, imported variables, or both.

To use a load-on-call DLL in your simple DLL application, perform the following steps:

Writing your DLL application code
Dynamic Link Libraries (DLLs)

Write your code as you would if the functions were statically bound. Assembler
code that will access imported functions and/or imported variables must use the
Language Environment macros.

Compiling your DLL application code
- Compile your C source files with the following compiler options:
  - DLL (not necessary if the XPLINK compiler option is specified)
  - RENT
  - LONGNAME
These options instruct the compiler to generate special code when calling
functions and referencing external variables.
- Compile your C++ source files normally. A C++ application is always DLL
code.
- Compile your COBOL source files with the following compiler options:
  - DLL
  - RENT
  - NOEXPORTALL
- Compile your VisualAge PL/I source files normally. The VisualAge PL/I
  compiler always generates DLL-enabled code.
- Assembler DLL Application source files must be assembled using the GOFF
  option.

Binding your DLL application code
- The binder option CASE(MIXED) is required when binding DLLs applications
  that use mixed-case exported names.
- The binder options RENT, DYNAM(DLL), and COMPAT(PM3) or
  COMPAT(CURRENT) are required.

Include the definition side-deck from the DLL provider in the set of object
modules to bind. The binder uses the definition side-deck to resolve references
to functions and variables defined in the DLL. If you are referencing multiple
DLLs, you must include multiple definition side-decks.

Note: Because definition side-decks in automatic library call (autocall)
processing will not be resolved, you must use the INCLUDE statement.

After final autocall processing of DD SYSLIB is complete, all DLL-type references that
are not statically resolved are compared to IMPORT control statements. Symbols on
IMPORT control statements are treated as definitions, and cause a matching
unresolved symbol to be considered dynamically rather than statically resolved. A
dynamically resolved symbol causes an entry in the binder B_IMPEXP to be created.
If the symbol is unresolved at the end of DLL processing, it is not accessible at run

time.

Addresses of statically bound symbols are known at application load time, but
addresses of dynamically bound symbols are not. Instead, the run-time library that
loads the DLL that exports those symbols finds their addresses at application run
time. The run-time library also fixes up the importer’s linkage blocks (descriptors) in
C_WSA during program execution.

The following code fragment illustrates how a C++ application can use the TRIANGLE
DLL described previously (see “Writing Your C++ DLL Code” on page 55). Compile
normally and bind with the definition side-deck provided with the TRIANGLE DLL.
Dynamic Link Libraries (DLLs)

extern int getarea(); /* function prototype */
main() {
  ...
  getarea(); /* imported function reference */
  ...
}

The following COBOL code sample illustrates how a simple COBOL-only DLL application (A1C4DL01) calls a COBOL DLL (A1C4DL02):

```cobol
CBL PGMNAME(LONGMIXED),DLL,RENT
IDENTIFICATION DIVISION.
PROGRAM-ID. 'A1C4DL01'.
ENVIRONMENT DIVISION.
CONFIGURATION SECTION.
INPUT-OUTPUT SECTION.
FILE-CONTROL.
DATA DIVISION.
FILE SECTION.
WORKING-STORAGE SECTION.
  01 TODAYSDATE-YYYYMMDD         PIC 9(8).
PROCEDURE DIVISION.
  Display 'A1C4DL01: Entered'
  MOVE FUNCTION CURRENT-DATE(1:8) TO TODAYSDATE-YYYYMMDD
  Call 'A1C4DL02' using todays-date-yyyyymmd
  Display 'A1C4DL01: All done'
  GOBACK

CBL PGMNAME(LONGMIXED),DLL,EXPORTALL,RENT
IDENTIFICATION DIVISION.
PROGRAM-ID. 'A1C4DL02'.
ENVIRONMENT DIVISION.
CONFIGURATION SECTION.
INPUT-OUTPUT SECTION.
FILE-CONTROL.
DATA DIVISION.
FILE SECTION.
WORKING-STORAGE SECTION.
  01 TODAYSDATE-YYYYMMDD         PIC 9(8).
PROCEDURE DIVISION using todays-date-yyyyymmd.
  Display 'A1C4DL02: Todays date is ' todays-date-yyyyymmd
  GOBACK
.
```

Figure 26. COBOL DLL application calling a COBOL DLL

The following code fragment illustrates how an Assembler routine can use the ADLLBEV2 DLL described before in "Writing Your Language Environment-conforming Assembler DLL Code" on page 57. Assemble and bind with the definition side-deck provided with the ADLLBEV2 DLL.
Creating and Using DLLs

Figure 28 on page 64 summarizes the use of DLLs for both the DLL provider and for the writer of applications that use them. In this example, application ABC is referencing functions and variables from two DLLs, XYZ and PQR. The connection between DLL preparation and application preparation is shown. Each DLL shown contains a single compilation unit. The same general scheme applies for DLLs composed of multiple compilation units, except that they have multiple compiles and a single bind for each DLL. For simplicity, this example assumes that ABC does not export variables or functions and that XYZ and PQR do not use other DLLs.
DLL Restrictions

Consider the following restrictions when creating DLLs and DLL applications:

- The entry point for a DLL must be in a program compiled with a Language Environment-conforming compiler that includes DLL support capability. Otherwise, Language Environment issues an error and terminates the application.

- DLLs must be REENTRANT. Be sure to specify the RENT option when you bind your code. Unpredictable results will occur if you link-edit a DLL as NORENT.
One possible symptom you may see that indicates the DLL was link-edited as
NORENT is more than one writable static area for the same DLL.

- In a C/C++ DLL application that contains `main()`, `main()` cannot be exported.
- The AMODE of a DLL application must be the same as the AMODE of the DLL that it calls.
- DLL facilities are not available:
  - Under MTF, CSP or SP™ C
  - To application programs with `main()` written in PL/I that dynamically call C functions. (This restriction does not apply to VisualAge PL/I.)
- In C++ applications, you cannot implicitly or explicitly perform a physical load of a DLL while running static destructors. However, a logical load of a DLL (meaning that the DLL has previously been loaded into the enclave) is allowed from a static destructor. In this case, references from the load module containing the static destructor to the previously-loaded DLL are resolved.
- You cannot use the C functions `set_new_handler()` or `set_unexpected()` in a DLL if the DLL application is expected to invoke the new handler or unexpected function routines.
- If a fetched C module is compiled as a DLL, it can import variables and functions from the other DLL modules, but it cannot export variables or functions.
- A COBOL dynamic call cannot be made to a load module that is a DLL.
- A COBOL dynamic call cannot be made to a COBOL for OS/390 & VM program that is compiled with the DLL compiler option.
- COBOL data declared with the EXTERNAL attribute are independent of DLL support; these data items are managed by the COBOL run-time environment and are accessible by name from any COBOL program in the run-unit that declares them, regardless of whether the programs are in DLLs or not.

In particular, the facilities for exporting and importing external variables from DLLs implemented in C/C++ do not apply to COBOL external data.

- When using the explicit C DLL functions in a multithreaded environment, avoid any situation where one thread frees a DLL while another thread calls any of the DLL functions. For example, this situation occurs when a `main()` function uses `d11load()` or `dlopen()` to load a DLL, and then creates a thread that uses the `ftw()` function. The `ftw()` target function routine is in the DLL. If the `main()` function uses `dl1free()` or `dlclose()` to free the DLL, but the created thread uses `ftw()` at any point, you will get an abend.

To avoid a situation where one thread frees a DLL while another thread calls a DLL function, do either of the following:

- Do not free any DLLs by using `dl1free()` or `dlclose()` (Language Environment will free them when the enclave is terminated).
- Have the `main()` function call `dl1free()` or `dlclose()` only after all threads have been terminated.

- For C/C++ DLLs to be processed by IPA, they must contain at least one function or method. Data-only DLLs will result in a compilation error.

- The use of circular C++ DLLs may result in unpredictable behavior related to the initialization of non-local static objects. For example, if a static constructor (being run as part of loading DLL “A”) causes another DLL “B” to be loaded, then DLL “B” (or any other DLLs that “B” causes to be loaded before static constructors for DLL “A” have completed) cannot expect non-local static objects in “A” to be initialized (that is what static constructors do). You should ensure that non-local static objects are initialized before they are used, by coding techniques such as counters or by placing the static objects inside functions.
Dynamic Link Libraries (DLLs)

Improving Performance

This section contains some hints on using DLLs efficiently. Effective use of DLLs may improve the performance of your application.

- If you are using a particular DLL frequently across multiple address spaces, the DLL can be installed in the LPA or ELPA. When the DLL resides in a PDSE, the dynamic LPA services should be used. Installing in the LPA/ELPA may give you the performance benefits of a single rather than multiple load of the DLL.
- Group external variables into one external structure.
- When using z/OS UNIX avoid unnecessary load attempts.

Language Environment supports loading a DLL residing in the HFS or a data set. However, the location from which it tries to load the DLL first varies depending whether your application runs with the run-time option POSIX(ON) or POSIX(OFF).

If your application runs with POSIX(ON), Language Environment tries to load the DLL from the HFS first. If your DLL is a data set member, you can avoid searching the HFS directories. To direct a DLL search to a data set, prefix the DLL name with two slashes (/) as is in the following example:

```
//MYDLL
```

If your application runs with POSIX(OFF), Language Environment tries to load your DLL from a data set. If your DLL is an HFS file, you can avoid searching a data set. To direct a DLL search to the HFS, prefix the DLL name with a period and slash (./) as is done in the following example.

```
./mydll
```

**Note:** DLL names are case sensitive in the HFS. If you specify the wrong case for your DLL that resides in the HFS, it will not be found.

- For C/C++ IPA, you should only export subprograms (functions and C++ methods) or variables that you need for the interface to the final DLL. If you export subprograms or variables unnecessarily (for example, by using the EXPORTALL option), you severely limit IPA optimization. In this case, global variable coalescing and pruning of unreachable or 100% inlined code does not occur. To be processed by IPA, DLLs must contain at least one subprogram. Attempts to process a data-only DLL will result in a compilation error.
- The suboption NOCALLBACKANY of the C compiler option DLL is more efficient than the CALLBACKANY suboption. The CALLBACKANY option calls a Language Environment routine at run-time. This run-time service enables direct function calls. Direct function calls are function calls through function pointers that point to actual function entry points rather than function descriptors. The use of CALLBACKANY will result in extra overhead at every occurrence of a call through a function pointer. This is unnecessary if the calls are not direct function calls.

Building Complex DLLs

Before you attempt to build complex DLLs it is important to understand the differences between the terms DLL, DLL code, and DLL application, as described in "DLL Concepts and Terms" on page 44.

Note that not all source files that make up a DLL application have to be compiled with the DLL option. However, source files that reference exported functions and exported global variables must be compiled with the DLL option.
Dynamic Link Libraries (DLLs)

A key characteristic of a complex DLL or DLL application is that linking DLL code with non-DLL code creates it. The following are reasons you might compile your code as non-DLL:

1. Source modules do not use C or C++.
2. To prevent problems which occur when a non-DLL function pointer call uses DLL code. This problem takes place when a function makes a call through a function pointer that points to a function entry rather than a function descriptor.

For more information on building complex DLLs, see "z/OS C/C++ Programming Guide".
Chapter 5. Link-Editing, Loading, and Running under Batch

You process an application under batch by submitting batch jobs to the operating system. A job might consist of one or more of the following job steps:

- Compiling a program
- Link-editing an application
- Running an application

**Note:** The terms in this section having to do with linking (bind, binding, link, link-edit, and so forth) refer to the process of creating an executable program from object modules (the output produced by compilers and assemblers). The program used is the DFSMS program management binder. The binder extends the services of the linkage editor and is the default program provided for creating an executable. For linkage editor-specific information, see **z/OS DFSMS Program Management**.

IBM-supplied cataloged procedures allow you to compile, link-edit or load, and run an application without supplying all the job control language (JCL) required for a job step. For information about cataloged procedures, see Chapter 8, "Using IBM-Supplied Cataloged Procedures," on page 103. If the statements in the cataloged procedures do not match your requirements exactly, you can modify them or add new statements for the duration of a job.

The following section provides an overview of link-editing, loading, and running Language Environment-conforming applications under batch. For detailed information about link-editing, see **z/OS DFSMS Program Management**. For information about the Language Environment prelinker, see Appendix A, "Prelinking an Application," on page 569.

**Link-Editing Applications That Contain Fortran**

Several Fortran and C library routines have identical names. If your application contains any Fortran or assembler routine that uses a Fortran library routine, see "Resolving Library Module Name Conflicts between Fortran and C" on page 17 to resolve any potential name conflicts.

TSO/E has its own section on link-editing, loading, and running (see Chapter 6, "Creating and executing programs under TSO/E," on page 83).

z/OS UNIX has its own section on link-editing, loading, and running C applications (see Chapter 7, "Creating and Executing Programs using z/OS UNIX System Services," on page 93).

**Basic Link-Editing and Running under Batch**

This section describes how to accept and to override the default Language Environment run-time options under MVS.

**Accepting the Default Run-Time Options**

To run an existing object module under batch and accept all of the default Language Environment run-time options, use the following sample JOB with the Language Environment-provided link-edit and run cataloged procedure CEEWLG.
Running under Batch

(see CEEWLG — Link and Run a Language Environment-Conforming Non-XPLINK Program on page 109 for more information). The CEEWLG procedure identifies the Language Environment libraries that your object module needs to link-edit and run; you do not need to explicitly identify these in your JCL.

There is also a cataloged procedure, CEEXLR, for XPLINK. See CEEXLR — Link and Run a Language Environment-Conforming XPLINK Program on page 111.

//CEEWLG JOB
//*
//LINKGO EXEC CEEWLG
//LKED.SYSIN DD DSN='userid.MYLIB.OBJLIB(MYPROG)',...DISP=SHR
//*

Figure 29. Accepting the Default Run-Time Options under Batch

Overriding the Default Run-Time Options

In the following example, an object module called MYPROG is created and run using the cataloged procedure CEEWLG. The code in the example overrides the Language Environment defaults for the RPTOPTS and MSGFILE run-time options.

//CEEWLG JOB
//*
//LINKGO EXEC CEEWLG,
//   PARM.GO='RPTOPTS(ON),MSGFILE(OPTRPRT)/'
//*
//LKED.SYSIN DD DSN='userid.MYLIB.OBJLIB(MYPROG)',...DISP=SHR
//GO.OPTRPRT DD SYSOUT=A
//*

Figure 30. Overriding the Default Run-Time Options under Batch

The trailing slash after the run-time options is required for C, Fortran, PL/I and for COBOL users who have specified the CBLOPTS(OFF) run-time option. For COBOL users who have specified the CBLOPTS(ON) run-time option at installation (see z/OS Language Environment Programming Reference), the slash should go before the run-time options, as in the following:

: // PARM.GO='/RPTOPTS(ON),MSGFILE(OPTRPRT)'
:

Figure 31. Overriding the Default Run-Time Options for COBOL

Specifying Run-Time Options in the EXEC Statement

If the first program in your application is Language Environment-conforming or was compiled by a pre-Language Environment compiler supported by Language Environment, you can pass run-time options by using the PARM= parameter in your JCL. The general form for specifying run-time options in the PARM parameter of the EXEC statement is:

//[stepname] EXEC PGM=program_name,
//   PARM='[run-time options]/[program parameters]'
For example, if you want to generate a storage report and run-time options report for program PROGRAM1, specify the following:

```
//G01  EXEC  PGM=PROGRAM1,PARM='RPTSTG(ON),RPTOPTS(ON)/'
```

The run-time options that are passed to the main routine must be followed by a slash (/) to separate them from program parameters. For HLL considerations to keep in mind when specifying run-time options, see “Specifying Run-Time Options and Program Arguments” on page 121. The EXECOPS option for C and C++ is used to specify that run-time options passed as parameters at execution time are to be processed by Language Environment. The option NOEXECOPS specifies that run-time options are not to be processed from execution parameters and are to be treated as program parameters.

For z/OS C/C++, a user can specify either EXECOPS or NOEXECOPS in a #pragma runopts directive or as a compiler option. EXECOPS is the default for z/OS C/C++. When EXECOPS is in effect, you can pass run-time options in the EXEC statement in your JCL.

For VisualAge PL/I and PL/I for MVS & VM, run-time options can be passed in your JCL if a PROCEDURE statement includes the OPTIONS(MAIN) clause. If the PROCEDURE statement specifies OPTIONS(MAIN NOEXECOPS), then run-time options cannot be passed in your JCL. Note that no PL/I compiler has an NOEXECOPS or EXECOPS compiler option, but they have the equivalent function by the specification of NOEXECOPS along with OPTIONS(MAIN).

---

### Providing Link-Edit Input

Input to the link-edit process can be:

- One or more object modules
- Control statements for the link-edit process
- Previously link-edited executable programs you want to combine into a single executable module
- A DLL side-deck if your application implicitly references DLL functions or data

[Figure 32 on page 72](#) shows the basic batch link-edit process for your application.
Writing JCL for the Link-Edit Process

You can use cataloged procedures rather than supply all the JCL required for a job step. You can use JCL statements to override the statements of the cataloged procedure to tailor the information provided by the link-edit process.

For a description of the IBM-supplied cataloged procedures that include a link-edit step, see Table 15 on page 105.

- **Invoking with the EXEC Statement**
  Use the EXEC job control statement in your JCL to invoke the binder. The EXEC statement is:
  ```
  //LKED EXEC PGM=HEWL
  ```

- **Using the PARM Parameter**
  Use the PARM parameter of the EXEC job control statement to select one or more of the optional facilities provided by the binder. For example, if you want a mapping of the executable program produced by the link-edit process, specify:
  ```
  //LKED EXEC PGM=HEWL,PARM='MAP'
  ```

For a description of link-edit options, see "Link-Edit Options" on page 77.

- **Required DD Statements**
  The link-edit process requires three standard data sets. You must define these data sets in DD statements with the ddnames SYSLIN, SYSLMOD, and SYSPRINT. If the linkage editor is being used then an additional data set must be defined with ddname SYSUT1. The required data sets and their characteristics are shown in Table 8 on page 73.
Table 8. Required Data Sets Used for Link-Editing

<table>
<thead>
<tr>
<th>ddname</th>
<th>Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYSLIN</td>
<td>Input</td>
<td>Primary input to the link-edit process consists of a sequential data set, members from a PDS or PDSE, or an in-stream data set. The primary input must be composed of one or more separately compiled object modules or link-edit control statements. An executable program cannot be part of the primary input, although it can be introduced by the INCLUDE control statement (see “Using the INCLUDE Statement” on page 76).</td>
</tr>
<tr>
<td>SYSLMOD</td>
<td>Output</td>
<td>The data set where output (executable program) from the link-edit process is stored.</td>
</tr>
<tr>
<td>SYSPRINT</td>
<td>Output</td>
<td>SYSPRINT defines the location for the listing that includes reference tables for the executable program. Output from the link-edit process:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Diagnostic messages</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Informational messages</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Module map</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Cross-reference list</td>
</tr>
<tr>
<td>SYSUT1</td>
<td>Utility</td>
<td>A data set used by the linkage editor as a temporary workspace (the data set must be on a direct access device). This data set is not required for the binder.</td>
</tr>
</tbody>
</table>

- Optional DD Statements
  If you want to use the automatic call library, you must define a data set using a DD statement with the name SYSLIB. You can also specify additional data sets containing object modules and executable programs as additional input to the link-edit process. These data set names and their characteristics are shown in Table 9 on page 74.
Running under Batch

### Table 9. Optional Data Sets Used for Link-Editing

<table>
<thead>
<tr>
<th>ddname</th>
<th>Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYSLIB1</td>
<td>Library</td>
<td>Secondary input to the linkage editor consists of object modules or load modules that are included in the executable program from the automatic call library. The automatic call library contains load modules or object modules that are used as secondary input to the linkage editor to resolve external symbols left undefined after all the primary input has been processed. The automatic call library can include:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Libraries that contain object modules, with or without linkage editor control statements</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• Libraries that contain executable programs</td>
</tr>
<tr>
<td></td>
<td></td>
<td>• The libraries that contain the Language Environment resident routines, such as SCEELKED, SCEELKEX, SCEEOBJ, and SCEECPP (for a description of these data sets see “Planning to Link-Edit and Run” on page 8).</td>
</tr>
<tr>
<td></td>
<td></td>
<td>SYSLIB is input to the linkage editor only if the CALL=NO link-edit option is not in effect (see Table 10 on page 77 in z/OS DFSMS Program Management, or z/OS TSO/E Command Reference for more information). You can also identify secondary input to the linkage editor with the INCLUDE statement.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>A routine compiled with a Language Environment-conforming compiler cannot be executed until the appropriate Language Environment resident routines have been linked into the executable program. The Language Environment resident routines are contained in the SCEELKED library; the data set name could be CEE.SCEELKED. If you are unsure where SCEELKED has been installed at your location, contact your system administrator. This data set must be specified in the SYSLIB statement in your JCL.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>In the following example, the SYSLIB DD statement is written so that Language Environment resident library routines are included as secondary input into your executable program:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>//SYSLIB DD DSNAME=CEE.SCEELKED,DISP=SHR</td>
</tr>
</tbody>
</table>

#### Notes:

1. Required for library run-time routines
2. Optional data set

- Examples of Link-Edit JCL

A typical sequence of job control statements for link-editing an object module (compiled NOXPLINK) into an executable program is shown in Figure 33 on page 75. The NAME linkage editor control statement in the figure puts PROGRAM1 in USER.LOADLIB with the member name PROGRAM1.
A similar sequence of job control statements for link-editing an XPLINK object module is shown in Figure 34.

Figure 33. Creating a Non-XPLINK Executable Program under Batch

A similar sequence of job control statements for link-editing an XPLINK object module is shown in Figure 34.

Figure 34. Creating an XPLINK Executable Program under Batch

- Adding Members to a Library
  The output from the binder is usually placed in a private program library.
  The automatic call library that is used as input to the binder can be a Language Environment library (for example, SCEELKED/SCEEKEX for non-XPLINK applications, and SCEEBND2 for XPLINK applications), a compiler library, a private program library, or a subroutine library.
  When you are adding a member to a library, you must specify the member name as follows:
  - When a single module is produced as output from the linkage editor, the member name can be specified as part of the data set name in the SYSLMOD.
  - When more than one module is produced as output from the linkage editor, the member name for each module must be specified in the NAME option or the NAME control statement. The member name cannot be specified as part of the data set name.
- Link-Editing Multiple Object Modules
  When a VisualAge PL/I or PL/I for MVS & VM main procedure is link-edited with other object modules produced by the VisualAge PL/I or the PL/I for MVS & VM compilers, the entry point of the resulting executable program is resolved to the external symbol CEESTART. This happens automatically because the CEESTART CSECT is generated first in the object module and is specified in the
RUNNING UNDER BATCH

The following sections describe when and how to use the INCLUDE and LIBRARY control statements with the binder.

Using the INCLUDE Statement

Use the INCLUDE control statement to specify additional object modules or executable programs that you want included in the output executable program. Figure 35 contains an example of how to link-edit the CEEUOPT CSECT with your application. In the example, CEEUOPT is used to establish application run-time option defaults; see Chapter 9, “Using Run-Time Options,” on page 117 for more information.

```
//SYSLIB DD DSNAME=CEE.SCEELKED,DISP=SHR
//SYSLIN DD DSNAME=USER.OBJLIB(PROGRAM1),DISP=SHR
// DD DDNAME=SYSIN
//SYSLIN DD *
  INCLUDE SYSLIB(CEEUOPT)
```

Figure 35. Using the INCLUDE Linkage Editor Control Statement

Using the LIBRARY Statement

Use the LIBRARY statement to direct the binder to search a library other than that specified in the SYSLIB DD statement. This method resolves only external references listed on the LIBRARY statement. All other unresolved external references are resolved from the library in the SYSLIB DD statement.

In Figure 36 on page 77 the LIBRARY statement is used to resolve the external reference PROGRAM2 from the library described in the TESTLIB DD statement.
Data sets specified by the INCLUDE statement are incorporated as the linkage editor encounters the statement. In contrast, data sets specified by the LIBRARY statement are used only when there are unresolved references after all the other input is processed.

### Link-Edit Options

SYSLMOD and SYSPRINT are the data sets used for output. The output varies, depending on the options you select, as shown in Table 10. The underlined options are the defaults.

<table>
<thead>
<tr>
<th>Option</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>XREF</td>
<td>NOXREF</td>
</tr>
<tr>
<td>LIST</td>
<td>NOLIST</td>
</tr>
<tr>
<td>NCAL</td>
<td>CALL</td>
</tr>
<tr>
<td>PRINT</td>
<td>NOPRINT</td>
</tr>
<tr>
<td>MAP</td>
<td>NOMAP</td>
</tr>
<tr>
<td>RENT</td>
<td>NORENT</td>
</tr>
</tbody>
</table>

You always receive diagnostic and informational messages as the result of link-editing, even if you do not specify any options. You can get the other output items by specifying options in the PARM parameter of the EXEC statement in your JCL for link-editing. See "Writing JCL for the Link-Edit Process" on page 72 for more information.

For more information about link-edit options, see z/OS DFSMS Program Management.

---

//SYSLIN DD DSN=USER.OBJLIB(PROGRAM1),DISP=SHR
// DD DNAME=SYSIN
//TESTLIB DD DSN=USER.TESTLIB,DISP=SHR
//SYSIN DD *
* LIBRARY TESTLIB(PROGRAM2)
*/

Figure 36. Using the LIBRARY Linkage Editor Control Statement

Data sets specified by the INCLUDE statement are incorporated as the linkage editor encounters the statement. In contrast, data sets specified by the LIBRARY statement are used only when there are unresolved references after all the other input is processed.

Chapter 5. Link-Editing, Loading, and Running under Batch
Loading Your Application Using the Loader

Your input to the loader can be:

- One or more HLL object modules
- One or more previously link-edited HLL load modules that you want to combine into a single load module
- A combination of both

If you include any linkage control statements (such as LIBRARY or INCLUDE) as input to the loader, an informational error message is printed in the output listing only if you have a SYSLOUT DD statement in your input JCL (see Figure 38 on page 81). Otherwise, the linkage control statements are ignored.

In basic loader processing, as shown in Figure 37, the loader accepts data from its primary input source, a data set defined by the SYSLIN DD statement. This data set is the object module produced by the compiler. The loader uses the external symbol dictionary in SYSLIN to determine whether the object module includes any external references that have no corresponding external symbols in SYSLIN.

The loader searches the automatic call library, SYSLIB, (as shown in Figure 37) for the routines in which the external symbols are defined and includes them in the load module if they exist. If all external references are resolved, the load module is executed.

Your application cannot be executed until the appropriate run-time routines have been included.

---

**Figure 37. Basic Loader Processing**
Writing JCL for the Loader

If you use cataloged procedures (rather than supply all of the JCL required for a job step that invokes the loader), you should be familiar with JCL statements for the loader so you can make the best use of the loader and, if necessary, override the statements of the cataloged procedure.

The following sections describe the basic JCL statements for loading. For a description of the IBM-supplied cataloged procedures that include a loader step, see Table 15 on page 105.

Invoking the Loader with the EXEC Statement

Use the EXEC statement to invoke the loader. The EXEC statement to invoke the loader is:

```
//GO EXEC PGM=LOADER
```

Using the PARM Parameter for Loader Options

Use the PARM parameter of the EXEC statement to specify loader options in your JCL for loader processing. For example, if you want your application to run even if abnormal conditions are detected, and you want a mapping of the executable program, specify the following:

```
//GO EXEC PGM=LOADER,PARM='MAP,LET'
```

Requesting Loader Options

Table 11 shows you which options you can specify as PARM parameters when running the loader. The underlined options are the defaults.

<table>
<thead>
<tr>
<th>Option</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAP</td>
<td>NOMAP</td>
</tr>
<tr>
<td>LET</td>
<td>NOLET</td>
</tr>
<tr>
<td>CALL</td>
<td>NOCALL</td>
</tr>
<tr>
<td>EP=name</td>
<td>Specifies the name of the entry point of the application being loaded.</td>
</tr>
<tr>
<td>PRINT</td>
<td>NOPRINT</td>
</tr>
<tr>
<td>RES</td>
<td>NORES</td>
</tr>
<tr>
<td>SIZE=size</td>
<td>Specifies the amount of storage allocated by loader processing; size includes the size of your executable program.</td>
</tr>
</tbody>
</table>

When you run the loader, you can request the options shown in Table 11 using the PARM parameter of the EXEC statement. For more information about specifying and using loader options, see z/OS DFSMS Program Management.

Passing Parameters through the Loader

Code the PARM parameter as follows:

```
PARM='[loader-options] [/run-time-options] [/pgmparm]'`

Chapter 5. Link-Editing, Loading, and Running under Batch 79
Running under Batch

where loader-options is a list of loader options, run-time-options is a list of run-time options, and pgmparm is a parameter string passed to the main routine of the application to run. The following examples refer to the routine parameter as PP. If you specify NOEXECOPS on the main routine, you must omit the slash in front of pgmparm.

If you specify loader options and either run-time options or a routine parameter (or both) in the PARM parameter, the loader options are given first and are separated from the run-time options or routine parameter by a slash. If there are loader options but no run-time options or routine parameters, the slash is omitted. If there are only run-time options or routine parameters, you must code the slash or slashes. If there is more than one option, separate the option keywords by commas.

The PARM field can have one of the following formats:
- If you use the special characters / or =, you must enclose the field in single quotes. For example:
  
  PARM='MAP,EP=FIRST/RPTOPTS(ON)/PP'
  PARM='MAP,EP=FIRST'
  PARM='/PP'
- If you do not use the / or = characters, and there is more than one loader option, you must enclose the options in parentheses. For example:
  PARM=(MAP,LET)
- If you do not use the / or = characters, and there is only one loader option, neither quotes nor parentheses are required. For example:
  PARM=MAP

Using DD Statements for the Standard Loader Data Sets

The loader always requires one standard data set, defined by the SYSLIN DD statement. Three other standard data sets are optional, and, if you use them, you must define them in DD statements with the names SYSOUT, SYSPRINT, and SYSLIB. The four data set names and characteristics are shown in Table 12.

<table>
<thead>
<tr>
<th>ddname</th>
<th>Type</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYSLIN</td>
<td>Input</td>
<td>Primary input data (normally the compiler output)</td>
</tr>
<tr>
<td>SYSLOUT</td>
<td>Output</td>
<td>Loader messages and module map listing</td>
</tr>
<tr>
<td>SYSPRINT</td>
<td>Output</td>
<td>Run-time messages and problem output listing</td>
</tr>
<tr>
<td>SYSLIB</td>
<td>Library</td>
<td>Automatic call library</td>
</tr>
</tbody>
</table>

[Figure 38 on page 81] is an example of the general job control procedure for creating and running an executable program under batch.
Running an Application under Batch

Under batch, you can request the execution of an executable program in an EXEC statement in your JCL. The EXEC statement marks the beginning of each step in a job or procedure, and identifies the executable program or cataloged procedure that executes.

The general form of the EXEC statement is:

```
//[stepname] EXEC PGM=program_name
```

The `program_name` is the name of the member or alias of the program to be executed. The specified program must be one of the following:

- An executable program that is a member of a private library specified in a STEPLIB DD statement in your JCL.
- An executable program that is a member of a private library specified in a JOBLIB DD statement in your JCL.
- An executable program that has been loaded into shared system storage, either the Link Pack Area (LPA) or the Extended Link Pack Area (ELPA).
- An executable program that is a member of a system library. Examples of system libraries are SYS1.LINKLIB and libraries specified in the LNKLST.

Unless you have indicated that the executable program is in a private library, it is assumed that the executable program is in a system library and the system libraries are searched for the name you specify.

Program Library Definition and Search Order

You can define the library in a DD statement in the following ways:

- With the dname STEPLIB at any point in the job step. The STEPLIB is searched before any system library or JOBLIB specified in a JOBLIB DD statement for the job step in which it appears (although an executable program can also be passed to subsequent job steps in the usual way). When a STEPLIB and JOBLIB are both present, the STEPLIB is searched for the step in which it appears and, for that step, the JOBLIB is ignored.

The system searches for executable programs in the following order of precedence:

1. Library specified in STEPLIB statement
2. Library specified in JOBLIB statement
3. LPA or ELPA

Figure 38. JCL for Creating an Executable Program
Running under Batch

4. The system library SYS1.LINKLIB and libraries concatenated to it through the active LNKLSTxx member of SYS1.PARMLIB

In the following example, the system searches USER.LOADLIB for the routine PROGRAM1 and USER.LOADLIB2 for the routine PROGRAMA:

```
//JOB8  JOB  DAVE,MSGLEVEL=(2,0)
//STEP1  EXEC  PGM=PROGRAM1
//STEPLIB DD  DSNAME=USER.LOADLIB,DISP=SHR
// STEP2  EXEC  PGM=PROGRAMA
//STEPLIB DD  DSNAME=USER.LOADLIB2,DISP=SHR
```

- With the ddname JOBLIB immediately after the JOB statement in your JCL. This library is searched before the system libraries. If any executable program is not found in the JOBLIB, the system looks for it in the system libraries.

In the following example, the system searches the private library USER.LOADLIB for the member PROGRAM1, reads the member into storage, and executes it.

```
//JOB8  JOB  DAVE,MSGLEVEL=(2,0)
//JOBLIB DD  DSNAME=USER.LOADLIB,DISP=SHR
//STEP1  EXEC  PGM=PROGRAM1
```

Specifying Run-Time Options

Each time your application runs, a set of run-time options must be established. These options determine many of the properties of how the application runs, including its performance, error handling characteristics, storage management, and production of debugging information. Under batch, you can specify run-time options in any of the following places (for additional information about the ways to specify run-time options, see "Specifying Run-Time Options" on page 117):

- In the CEEDOPT CSECT, where the installation default options are located (for more information, see "CEEDOPT Invocation Syntax" on page 124).
- In the CEEROPT CSECT, where region-wide installation default options are located (for more information, see "CEEROPT Invocation Syntax" on page 124).

Restriction: CEEROPT is valid under CICS, or IMS with LRR.

- In the CEEUOPT CSECT where user-supplied default options are located (for more information, see "CEEDOPT Invocation Syntax" on page 124).
- `#pragma runopts` in C/C++ source code (for more information, see page 119).
- In a PLIXOPT string in PL/I source code (for more information, see page 119).
- In the PARM parameter of the EXEC statement in your JCL.
- In z/OS on the GPARAM parameter of the IBM-supplied cataloged procedure (for more information, see "z/OS C/C++ User's Guide").
- In the assembler user exit (for more information, see "CEEBXITA Assembler User Exit Interface" on page 463).
- In the _CEE_RUNOPTS environment variable, when your application is running under z/OS UNIX and is invoked by one of the exec family of functions.
Chapter 6. Creating and executing programs under TSO/E

Under TSO/E, you process an application by compiling and link-editing the programs that make up the application, and then running the application.

The compiler produces an object module; the link-edit process takes the object module and produces an executable program. You can link-edit and run your application as separate steps (LINK and CALL) or you can link-edit and run your application as a single step (LOADGO).

**Link-Editing Applications that Contain Fortran**
Several Fortran and C library routines have identical names. If your application contains any Fortran or assembler routine that uses a Fortran library routine, see "Resolving Library Module Name Conflicts between Fortran and C" on page 17 to resolve any potential name conflicts.

---

Basic link-editing and running under TSO/E

This section describes how to accept and to override the default Language Environment run-time options under TSO/E.

**Accepting the default run-time options**

Use the LOADGO command to run an existing NOXPLINK-compiled object module under TSO/E and to accept the default Language Environment run-time options. See "Specifying Run-Time Options and Program Arguments" on page 121 for more information on using run-time options. For example, the command

```
LOADGO ('userid.MYLIB.OBJLIB(MYPROG)') LIB ('CEE.SCEELKED')
```

does the following:

- Takes the existing object module MYPROG from the object library in which you have it stored
- Links in the Language Environment (text) link library SCEELKED
- Runs the new executable program

**Overriding the default run-time options**

The following example overrides the Language Environment defaults for the RPTPTS and MSGFILE run-time options, and loads and runs the XPLINK-compiled program MYPROG:

```
LOADGO ('userid.MYLIB.OBJLIB(MYPROG)') 'RPTOPTS(ON), MSGFILE(OPTRPRT)/' LIB ('CEE.SCEEBIND')
```

The Language Environment data sets SCEELKED link library, SCEEBIND2 link library, and the SCEERUN dynamic library (needed before you can run your executable program) could have been installed with a different high-level qualifier than CEE. Check with your system administrator for the correct names.

The LOADGO command is described in detail in "Loading and running using the LOADGO command" on page 88.

---

© Copyright IBM Corp. 1995, 2004 83
Running under TSO/E

Link-editing and running

The LINK command link-edits a compiled external procedure or combines two or more procedures to form a single executable program. You can run an executable program by using the CALL command. Use the LINK-and-CALL method of processing when you want to:

- Keep a copy of the executable program in an external data set
- Link-edit two or more external procedures to form a single executable program
- Run a program repeatedly, without changing the source code

To run a compiled program without keeping a copy of the executable program, use the LOADGO command.

Link-editing your application using the LINK command

The LINK command invokes the linkage editor, which converts one or more object modules into an executable program suitable for execution. Later, you can run the executable program using the CALL command (see "Using the CALL command to run your application" on page 87). The general form of the LINK command is:

```
LINK (data-set-list) [LOAD (data-set-name)]
```

```
LIB (data-set-list) [options]
```

**LINK** *(data-set-list)*

Specifies the names of the data sets containing the object modules to be link-edited. The variable *data-set-list* must contain at least one object module, but can also contain binder control statements. If you have only one name, you can omit the parentheses. If there are several names, you must separate them by commas or blanks within the parentheses. The rules for positioning control statements in relation to object modules are the same as for batch mode. If you specify a simple data set name, the system assumes the descriptive qualifier OBJ; that is, the data set name is of the form *userid.data-set-name.OBJ.*

**LOAD** *(data-set-name)*

Specifies the name of the data set to contain the executable program generated by the link-edit process. If you specify a simple name, the system adds the user-identification qualifier and the descriptive qualifier LOAD (*userid.data-set-name.LOAD*), and uses that as the data set name. The resulting executable program must be stored as a member in a PDS or PDSE. If you do not supply a member name, the executable program is placed in *member* TEMPNAME of the *userid.data-set-name.LOAD* data set. If you do not specify LOAD, *userid.LOAD* is used.

**LIB** *(data-set-list)*

Specifies the names of data sets that contain user-supplied modules that you want to be link-edited by the automatic library call facility.

The appropriate link-edit libraries, including the Language Environment link-edit libraries, must be specified. See "Planning to Link-Edit and Run" on page 8 for a description of the Language Environment link-edit libraries.
options
Specifies a list of link-edit processing options. You must separate the options with a valid delimiter such as a comma or blank. Table 14 on page 90 contains a partial listing of available link-edit options.

The following example shows how to:

- Link-edit two object modules named PROGRAM1 and CEEUOPT. CEEUOPT can be used to establish programmer run-time option defaults. See Chapter 9, "Using Run-Time Options," on page 117 for more information.
- Load the resulting executable program in member PROGRAM1 in the library USER.LOADLIB.
- Specify the Language Environment library CEE.SCEELKED as the automatic call library for a non-XPLINK application.
- Generate a mapping of the executable program that is run by using the MAP option.
- Direct the linkage editor listing to the terminal by using the PRINT(\*) option.

```
LINK ('USER.OBJLIB(PROGRAM1)','USER.OBJLIB(CEEUOPT)')
LOAD('USER.LOADLIB(PROGRAM1)')
LIB ('CEE.SCEELKED') MAP PRINT(*)
```

For more information about using the TSO/E LINK command and its options, see z/OS TSO/E Command Reference.

Using CMOD CLIST to invoke the TSO/E LINK command

You can use CMOD to build C modules or C ILC applications where C is the main routine. CMOD invokes the TSO/E LINK command by passing all CMOD parameters to that command. Any parameters not passed from CMOD have the normal LINK command default values. The CMOD CLIST resides in CEE.SCEECLST. The CMOD CLIST cannot be used to link XPLINK applications.
Syntax

**OBJ**
Specifies input object data set names.

**LOPT**
Specifies a string of linkage editor options.

**LIB**
Specifies libraries that you want to use to resolve external references. These libraries are appended to the default C library functions.

**LOAD**
An output data set name. If you do not specify an output data set name, a name is generated for you. The name generated by the CLIST consists of your user prefix followed by LOAD(TEMPNAME).

Table 13 shows CMOD calls and their corresponding results:

<table>
<thead>
<tr>
<th>Call</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmod obj(myobj)</td>
<td>link userid.myobj lib(cee.sceelked)</td>
</tr>
<tr>
<td>cmod obj(myobj) lib (mylib)</td>
<td>link userid.myobj lib(userid.mylib cee.sceelked) rmode(24) amode(24)</td>
</tr>
<tr>
<td>lopt(rmode(24)</td>
<td>lopt(amode(24))</td>
</tr>
<tr>
<td>cmod obj(myobj) lib (mylib)</td>
<td>link userid.myobj lib(userid.mylib cee.sceelked) load(myload) amode(24)</td>
</tr>
<tr>
<td>lopt(amode(24))</td>
<td></td>
</tr>
</tbody>
</table>

Possible error messages are:
Using the CALL command to run your application

The TSO/E CALL command loads and executes a specified executable program. To run an application successfully, the SCEERUN and SCEERUN2 dynamic libraries must be either in the link-list concatenation, or in a STEPLIB in the TSO/E logon procedure. As an alternative, the TSO/E Dynamic STEPLIB Facility (Program Offering 5798-DZW) can be used to dynamically allocate SCEERUN and SCEERUN2 to the execution environment. For more information about the TSO/E logon procedure, see [z/OS Program Directory](#).

When you use the CALL command, you must also specify the ALLOCATE command to dynamically allocate the data sets required by the application you intend to run. For more information, see [z/OS TSO/E Command Reference](#).

The general form of the CALL command is:

```plaintext
CALL data-set-name [membername] program_parms ASIS
```

**Syntax**

- `data-set-name`: Specifies the data set that holds the executable program. If you specify the simple name of the data set, the system assumes the descriptive qualifier LOAD. If you do not specify a member name, the system assumes the name TEMPNAME.

- `program_parms`: A list of run-time options and program parameters passed to the main routine. Use a slash (/) to separate the run-time options and program parameters.

- `ASIS`: Specifies that the program parameters are to be left in their original case. For C or C++, however, you must specify at least one lowercase character in the program parameter string for the case to be preserved, otherwise C or C++ lowers the string.

For example, if you want to load and run member PROGRAM1 located in the data set USER.LOADLIB, and pass run-time options that generate storage and run-time options reports, specify the following:

```plaintext
CALL 'USER.LOADLIB(PROGRAM1)' 'RPTSTG(ON),RPTOPTS(ON)/'
```

For a summary of formatting considerations for specifying run-time options, see “Specifying Run-Time Options and Program Arguments” on page 121.
Running under TSO/E

The EXECOPS option for C and C++ is used to specify that run-time options passed as parameters at execution time are to be processed by Language Environment. The option NOEXECOPS specifies that run-time options are not to be processed from execution parameters and are to be treated as program parameters. For z/OS C/C++, a user can specify either EXECOPS or NOEXECOPS in a #pragma runopts directive or as a compiler option. EXECOPS is the default for both z/OS C/C++ and z/OS C++. If EXECOPS is specified, any run-time options specified in the CALL command are treated as program parameters.

**Note:** When using CALL to execute a program in the background under TSO/E with PGM=IKJEFT01, the ABTERMENC(ABEND) run-time option will not be processed correctly. To provide ABEND support under TSO/E, use PGM=IKJEFT1A or PGM=IKJEFT1B. For more information regarding these entry points, see z/OS TSO/E Customization.

### TSO/E parameter list format

The TSO/E parameter list format differs depending on the language of the routine. Refer to Appendix D, “Operating System and Subsystem Parameter List Formats,” on page 593 for language-specific considerations.

### Loading and running using the LOADGO command

Use the LOADGO command to create an executable program in main storage and then run it. When the application has run, TSO automatically deletes the executable program created by LOADGO. The general form of the LOADGO command is:

```
LOADGO (data-set-list) 'program-parameter-string'
```

#### Syntax

- **LOADGO** *(data-set-list)*
  - Specifies the names of one or more object modules or executable programs that you want to load and run. If you have only one name, you can omit the parentheses. If you have several names, you must separate them by commas or blanks.
  - The names can be data set names, names of members of data sets, or both.

- **program-parameter-string**
  - Specifies run-time options and program parameters to be passed to the executable program at run time. Use a slash (/) to separate the run-time options and parameters that are passed to the main routine in the executable program. The possible combinations are described in “Specifying Run-Time Options and Program Arguments” on page 121.

- **LIB** *(data-set-list)*
  - Specifies the names of data sets containing user-supplied modules that you want the automatic library call facility to link-edit.
  - You must also list the Language Environment resident library (SCEELKED for non-XPLINK applications or SCEEBIND for XPLINK applications). SCEELKED
is installed into a data set with a high-level qualifier; for example, the name might be CEE.SCEELKED. If you are unsure of the name of the data set where SCEELKED has been installed at your location, contact your system administrator.

**options**

Specifies a list of loader options. You must separate the options with a valid delimiter such as a comma or blank space. For a description of loader options, see Table 14 on page 90 and [z/OS TSO/E Command Reference](#).

### Allocating data sets under TSO/E

When you use the LOADGO command under TSO/E, you must also specify the ALLOCATE command to dynamically allocate the data sets required by the application you intend to run. For more information, see [z/OS TSO/E Command Reference](#).

### Example of using LOADGO

The following example shows how to:

- Create an executable program using the object modules PROGRAM1 and CEEUOPT
- Specify the run-time options to produce the run-time options report (RPTOPTS) and the storage report (RPTSTG)
- Specify the Language Environment library CEE.SCEELKED as the automatic call library for a non-XPLINK application
- Generate a mapping of the executable program
- Direct the loader listing to the terminal

```
LOADGO ('USER.OBJLIB(PROGRAM1)','USER.OBJLIB(CEEUOPT)')
 'RPTOPTS(ON),RPTSTG(ON)/'
 LIB ('CEE.SCEELKED') MAP PRINT(+)
```

To run an application successfully under TSO/E, the SCEERUN dynamic library must be either in the link-list concatenation, or in a STEPLIB in the TSO/E logon procedure. As an alternative, the MVS/TSO Dynamic STEPLIB Facility (Program Offering 5798-DZW) can be used to dynamically allocate SCEERUN to the TSO/E execution environment. For more information about the TSO/E logon procedure, see [z/OS Program Directory](#).

The EXECOPS option for C and C++ is used to specify that run-time options passed as parameters at execution time are to be processed by Language Environment. The option NOEXECOPS specifies that run-time options are not to be processed from execution parameters and are to be treated as program parameters. For z/OS C/C++, a user can specify either option in a #pragma runopts statement. For both z/OS C/C++ and z/OS C++ users, the options can be specified as compiler options. EXECOPS is the default for both z/OS C/C++ and z/OS C++. When EXECOPS is in effect, you can specify run-time options in the LOADGO command.

### Link-edit and loader options

Table 14 on page 90 contains a partial listing of available link-edit and loader options.
### Running under TSO/E

#### Table 14. Selected Loader Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>CALL</td>
<td>CALL specifies that the data set specified in the LIB operand is to be searched to locate executable programs referred to by the module being processed. NOCALL specifies that the data set specified in the LIB operand is not to be searched to locate executable programs referred to by the module being processed. If NOCALL is specified, then RES is invalid.</td>
</tr>
<tr>
<td>SIZE(integer)</td>
<td>Specifies the size, in bytes, of the dynamic storage that the loader can use.</td>
</tr>
<tr>
<td>PRINT(data_set_name)</td>
<td>PRINT specifies the name of the data set that is used to contain the listing. You can direct output to the terminal by specifying PRINT(*).</td>
</tr>
<tr>
<td>MAP</td>
<td>MAP generates a map of the executable programs and places them in the PRINT data set.</td>
</tr>
<tr>
<td>LET</td>
<td>LET specifies that the loader attempts to execute your application even if an error of severity 2 or greater is found.</td>
</tr>
<tr>
<td>RES</td>
<td>RES specifies that the link pack area is to be searched for the executable program (referred to by the module being processed) before the specified libraries are searched. If you also specify the NOCALL operand, the RES option is not valid. NORES specifies that the link pack area is not to be searched for the executable program referred to by the module being processed.</td>
</tr>
</tbody>
</table>

### Using the iconv utility and ICONV CLIST for C/C++

The `iconv` utility uses the `iconv_open()`, `iconv()`, and `iconv_close()` functions to convert the input file records from the coded character set definition for the input code page to the coded character set definition for the output code page. There is one record in the output file for each record in the input file. No padding or truncation of records is performed.

The `iconv` utility can also perform BiDi layout transformation (for example, shaping and reordering) on the data to be converted according to the two environment variables, `_BIDION` and `_BIDIATTR`. See “Bidirectional Language Support” in [z/OS C/C++ Programming Guide](https://www.ibm.com/z/os/zos/bkserv/c/cpguide/) for more information on BiDi layout transformation. See “Using Environment Variables” in [z/OS C/C++ Programming Guide](https://www.ibm.com/z/os/zos/bkserv/c/cpguide/) for a description of _BIDION and _BIDIATTR.

When conversions are performed between single-byte code pages, the output records are the same length as the input records. When conversions are performed
between double-byte code pages, the output records could be longer or shorter than the input records because the shift-out and shift-in characters could be added or removed.

The ICONV CLIST invokes the `iconv` utility to copy the input data set to the output data set and convert the characters from the input code page to the output code page.

### Using the genxlt utility and GENXLT CLIST for C/C++

The `genxlt` utility reads character conversion information from an input file and writes the compiled version to an output file. The input file contains directives that are acted upon by the `genxlt` utility to produce the compiled version of the conversion table. See the [z/OS C/C++ User’s Guide](#) for more information on the `genxlt` utility.

The GENXLT CLIST invokes the `genxlt` utility to read the character conversion information and produce the conversion table. It then invokes the system linkage editor to build the executable program.

### Running your application under TSO/E

You can run your TSO/E application in the following ways:

- Use LOADGO to create a module in main storage and then run it. For a description of the LOADGO command, see "Loading and running using the LOADGO command" on page 88.
- Use the CALL command to run an executable program that you have created using LINK. For a description of the LINK command, see "Link-editing your application using the LINK command" on page 84. For a description of the CALL command, see "Using the CALL command to run your application" on page 87.
- Run your application as a command processor.
Running under TSO/E
Chapter 7. Creating and Executing Programs using z/OS UNIX System Services

The interface to the linkage editor for z/OS UNIX System Services (z/OS UNIX) C applications is the z/OS UNIX c89 utility or the cc utility, and for C++ applications it is the c++ utility. You can use them to compile and link-edit a z/OS UNIX C/C++ program in one step, or link-edit application object modules after the compilation. You must, however, invoke one of the z/OS UNIX shells before you can run the c89 utility. For more information on using these utilities, see z/OS UNIX System Services Command Reference.

Fortran applications are not supported under z/OS UNIX. When POSIX threading services are used, Fortran routines can only run in the initial process thread (IPT).

COBOL programs are supported under z/OS UNIX. See Running COBOL Programs under z/OS UNIX on page 98 for more information.

VisualAge PL/I has support for z/OS UNIX that is essentially the same as that of C++. Therefore everything in this chapter that applies to C++ is also applicable to VisualAge PL/I.

PL/I for MVS & VM routines are supported under z/OS UNIX. PL/I for MVS & VM routines can run in the IPT without any unique restrictions other than those described in Enterprise PL/I for z/OS and OS/390 Migration Guide. PL/I for MVS & VM routines can run in the non-IPTs created by C/C++ routines with some restrictions. Limited PL/I - C/C++ ILC is supported in non-IPTs. See "Basic Link-Editing and Running PL/I Routines under z/OS UNIX with POSIX(ON)" on page 99 for more information.

PL/I MTF applications require z/OS UNIX services. PL/I MTF applications do not support ILC with C/C++ and must not invoke any z/OS UNIX services through an assembler program; otherwise the results are unpredictable.

Basic Link-Editing and Running C/C++ Applications under z/OS UNIX

z/OS UNIX supports the following environments for running your z/OS UNIX C/C++ applications:

- z/OS UNIX shells
- TSO/E
- Batch
- z/OS UNIX shells through MVS batch

Using the z/OS UNIX-supplied utilities c89/cc/c++, you can compile and link-edit a z/OS UNIX C/C++ application in one step, or link-edit application object modules separately. To produce an executable file, invoke c89 and pass it object modules (file.o HFS files or file.0BJ MVS data sets) without using the -c option.

See z/OS UNIX System Services Command Reference for information on the c89 utility.
Invoking a Shell from TSO/E

To begin a z/OS UNIX shell session, you first log on to TSO/E and then invoke the TSO/E OMVS command. This starts a login shell, from which you can enter shell commands.

You can also login with rlogin or telnet.

See z/OS UNIX System Services User’s Guide for additional information on starting a shell session.

Using the z/OS UNIX c89 Utility to Link-Edit and Create Executable Files

To link-edit a z/OS UNIX C/C++ application’s object modules to produce an executable file, specify the c89 utility and pass it object modules (file.o HFS files or //file.OBJ MVS data sets). The c89 utility recognizes that these are object modules produced by previous C/C++ compilations and does not invoke the compiler for them.

To compile source files without link-editing them, use the c89 -c option to create object modules only. You can use the -o option with the command to specify the name and location of the executable file to be created.

For a complete description of all the c89 options, see z/OS UNIX System Services Command Reference.

- To link-edit an XPLINK-compiled application object module to create the mymodx.out executable file in the current directory, specify:
  c89 -o mymodx.out -Wl,xplink usersource.o
- To link-edit an application object module to create the default executable file a.out in the working directory, specify:
  c89 usersource.o
- To link-edit an application object module to create the mymod.out executable file in the app/bin directory, relative to your working directory, specify:
  c89 -o app/bin/mymod.out usersource.o
- To link-edit several application object modules to create the mymod.out executable file in the app/bin directory, relative to your working directory, specify:
  c89 -o app/bin/mymod.out usersrc.o ottrsrc.o "//PGM.OBJ(PW...APP)"
- To link-edit an application object module to create the MYLOADMD executable member of the MVS APPROG.LIB data set for your user ID, specify:
  c89 -o "//APPROG.LIB(MYLOADMD)" usersource.o
- To compile and link-edit an application source file with several previously compiled object modules to create the executable file zinfo in the approg/lib subdirectory, relative to your working directory, specify:
  c89 -o approg/lib/zinfo usersrc.c existobj.o "//PGM.OBJ(PWAPP)"

Running z/OS UNIX C/C++ Application Programs

This section discusses the different ways you can run your z/OS UNIX C/C++ applications under z/OS.
z/OS UNIX Application Program Environments

z/OS UNIX supports the following environments from which you can run your z/OS UNIX C/C++ applications:

- z/OS UNIX shells
- TSO/E

You cannot directly call a z/OS UNIX application that resides in an HFS file from the TSO/E READY prompt. However, you can do so with a TSO/E BPXBATCH command, and with a REXX EXEC.

- MVS batch

You cannot directly use the JCL EXEC statement to run a z/OS UNIX application program that resides in an HFS file because you cannot put an HFS filename on the JCL EXEC statement. However, by using the BPXBATCH program, you can run a z/OS UNIX application that resides in an HFS file. You supply the name of the program as an argument to the BPXBATCH program, which runs under MVS batch and invokes a z/OS UNIX shell environment. (BPXBATCH also lets you call a program directly without having to also run a shell.) You can also run a z/OS UNIX application that resides in an HFS file by calling a REXX EXEC to invoke it under MVS batch.

Placing an MVS Application Executable Program in the File System

If you have a z/OS UNIX C/C++ application executable file as a member in an MVS data set and want to place it in the HFS, you can use the OPUTX or OGETX z/OS UNIX TSO/E commands to copy the member into an HFS file. For a description of these commands, see z/OS UNIX System Services Command Reference. For examples of using these commands to copy data sets to HFS files, see z/OS UNIX System Services User’s Guide.

Restriction on Using 24-Bit AMODE Programs

You cannot run an AMODE(24) C/C++ application that resides in an HFS file. Any programs you intend to run from the file system must be AMODE(31), problem program state, PSW key 8 programs. If you plan to run an AMODE(24) C/C++ program from within an z/OS UNIX application, make sure the executable program resides in a MVS PDS or PDSE member. Any new z/OS UNIX C/C++ applications you develop should be AMODE(31). XPLINK-compiled applications must be AMODE(31), and they and will force the ALL31 run-time option to ON.

Running an MVS Executable Program from a z/OS UNIX Shell

If your z/OS UNIX C/C++ application resides in MVS data sets and you need to run the application executable program from within a shell, you can pass a call to the module to TSO/E. In many cases you can also use the tso utility. If you entered the shell from TSO/E using the OMVS command, you can use the TSO function key to pass the command to TSO/E. For example, if your executable program is myprog in data set my.loadlib, type the following (from the shell) to pass the command to TSO/E:

tso "call 'my.loadlib(myprog)"

When the program completes, the shell session is restored. You can also run an MVS program from a shell by associating it with an HFS file by using sticky-bit or external link. See z/OS UNIX System Services Command Reference for more information on the chmod and the ln commands.
Running under z/OS UNIX

Running POSIX-enabled Programs

There are different considerations for running POSIX-enabled programs depending on whether you are using a z/OS UNIX shell or are running outside the shell.

Running POSIX-enabled Programs Using a z/OS UNIX Shell

Issuing the Executable from a Shell: Before an HFS program can be run in a shell, it must be given the appropriate mode authority for a user or group of users. You can update the mode authority for an executable by using the chmod command. See [z/OS UNIX System Services Command Reference](https://www.ibm.com) for the format and description of chmod. Note that when c89 creates an executable, the file is given execute permission for all users.

After you have updated the mode authority, enter the program name from the shell command line. For example,

- if you want to run the program data_crunch from your working directory,
- you have the directory where the program resides defined in your search path, and
- you are authorized to run the program,

  enter:
  
data_crunch

When running such programs, you can specify invocation run-time options only by setting the environment variable _CEE_RUNOPTS before invoking the program. For example, under a z/OS UNIX shell you can use the export command as shown below:

  export _CEE_RUNOPTS="rpto(on)"

To further update the run-time options, you can issue another export.

Issuing a Setup Shell Script from a Shell: To run a z/OS UNIX shell script that sets up an z/OS UNIX executable file and then runs the program, you give the appropriate mode authority for a user or group of users to run it. You can update the mode authority (access permission) for a shell script file by using the chmod command. See [z/OS UNIX System Services Command Reference](https://www.ibm.com) for the format and description of chmod. After mode authority has been given, enter the script file name from the shell command line.

Running POSIX-enabled Programs Outside the z/OS UNIX Shells

Running an MVS Batch z/OS UNIX C/C++ Application File which is HFS-resident: To run a z/OS UNIX C/C++ executable application file from an HFS file under MVS batch, invoke the IBM-supplied BPXBATCH program either from TSO/E, or by using JCL or a REXX EXEC (not batch). BPXBATCH performs an initial user login to run a specified program from the shell environment.

Before you invoke BPXBATCH, you must have the appropriate privilege to read from and write to HFS files. You should also allocate STDOUT and STDERR HFS files for writing any program output, such as error messages. Allocate the standard files using the PATH options on either the TSO/E ALLOCATE command or the JCL DD statement.

For a detailed discussion of the BPXBATCH program syntax and its use, and an example of running shell utilities under MVS batch using the BPXBATCH program, see [z/OS UNIX System Services Command Reference](https://www.ibm.com)
Invoking BPXBATCH from TSO/E: You can invoke BPXBATCH from TSO/E in the following ways:
- From the TSO/E READY prompt
- From a CALL command
- As a REXX EXEC

If you want to run the /myap/base_comp application program from your user ID, direct its output to the file /myap/std/my.out. Write any error messages to the file /myap/std/my.err and copy the output and error data to MVS data sets. You could write a REXX EXEC similar to the following example:

```rexx
/* base_comp REXX exec */
"Allocate File(STDOUT) Path('/u/myu/myap/std/my.out')
 Pathopts(OWRONLY,OCREAT,OTRUNC)
 Pathmode(SIRWXU) Pathdisp(DELETE,DELETE)"
"Allocate File(STDERR) Path('/u/myu/myap/std/my.err')
 Pathopts(OWRONLY,OCREAT,OTRUNC)
 Pathmode(SIRWXU) Pathdisp(DELETE,DELETE)"

"BPXBATCH PGM /u/myu/myap/base_comp"

"Allocate File(output1) Dataset('MYAPPS.STD(BASEOUT)')"
"Ocopy Indd(STDOUT) Outdd(output1) Text Pathopts(OVERRIDE)"

"Allocate File(output2) Dataset('MYAPPS.STD(BASEERR)')"
"Ocopy Indd(STDERR) Outdd(output2) Text Pathopts(OVERRIDE)"
```

Enter the name of the REXX EXEC from the TSO/E READY prompt to invoke BPXBATCH. When the REXX EXEC completes, the STDOUT and STDERR allocated files are deleted.

Invoking BPXBATCH Using JCL: To invoke BPXBATCH using JCL, submit a job that executes an application program and allocates the standard files using DD statements. For example, if you want to run the /myap/base_comp application program from your user ID, direct its output to the file /myap/std/my.out. Direct any error messages to be written to the file /myap/std/my.err; code the JCL statements as follows:

```c
//jobname JOB ...
//stepname EXEC PGM=BPXBATCH,PARM='PGM /u/myu/myap/base_comp'
//STDOUT DD PATH='/u/myu/myap/std/my.out'
//   PATHOPTS=OVRONLY,OCREAT,OTRUNC,PATHMODE=SIRWXU
//STDERR DD PATH='/u/myu/myap/std/my.err'
//   PATHOPTS=OVRONLY,OCREAT,OTRUNC,PATHMODE=SIRWXU
```

Invoking the Spawn Syscall in a REXX EXEC from TSO/E: A REXX EXEC can directly call a program which resides in the HFS. This can be done by using the spawn() syscall. The following is an example of a REXX program which can be called from TSO/E.

```rexx
/* REXX */
RC = SYSCALLS('ON')
If RC<0 | RC>4 Then Exit RC
Address SYSCALL
fstdout = 'fstdout'
stderr = 'fstderr'
'open' fstdout O_RDWR+O_TRUNC+O_CREAT 700
stdout = RETVAL
'open' stderr O_RDWR+O_TRUNC+O_CREAT 700
stderr = RETVAL
map.0=-1
map.1=stdout
map.2=stderr
parm.0=1
```
Running under z/OS UNIX

parm1='/bin/c89'
'spawn /bin/c89 3 map. parm. ___environment.'
spid = RETVAL
serrno = ERRNO
If spid=-1 Then Do
  str = 'unable to spawn' parm1', errno='serrno
  'write' stderr 'str'
  Exit serrno
End
'waitpid (spid) waitid 0'
xrc = waitid.W_EXITSTATUS
If xrc<>0 Then Do
  str = parm1 'failed, exit status='xrc
  'write' stderr 'str'
End
Exit xrc

Running a z/OS UNIX C/C++ Application Program Which is not HFS-resident:
Submit a z/OS UNIX C/C++ application executable program (an executable file that is a MVS PDS or PDSE member) to run under the MVS batch environment using the JCL EXEC statement the same way you would submit a traditional C/C++ application. The POSIX(ON) run-time option should be specified.

Running COBOL Programs under z/OS UNIX

COBOL programs are supported under z/OS UNIX.

In order to use COBOL under z/OS UNIX, the COBOL programs must be compiled with the Enterprise COBOL for z/OS and OS/390 compiler, COBOL for OS/390 & VM compiler or the COBOL for MVS & VM compiler, and the programs must be compiled with the RENT compiler option.

You can compile and link-edit your COBOL programs in the z/OS UNIX shell with the cob2 command. The cob2 command is available with COBOL for OS/390 & VM V2R2 or Enterprise COBOL for z/OS and OS/390.

Alternatively, you can compile your programs in TSO or batch and have the object module written to an HFS file by using the PATH parameter instead of the DSNAME parameter for the SYSLIN DD. Once you have your object modules in an HFS file, you can use the c89 utility to create an executable file.

When you want to use COBOL programs under z/OS UNIX be aware of the following:
• When COBOL is the main routine of a z/OS UNIX process, parameters are not passed in the C argv and argc format. Instead the parameter list consists of three parameters passed by reference:
  1. Argument-count: a binary fullword integer containing the number of elements in each of the arrays that are passed as the second and third parameters.
  2. Argument-length-list: an array of pointers. The Nth entry in the array is the address of a fullword binary integer containing the length of the Nth entry in the Argument-list (the third argument).
  3. Argument-list: an array of pointers. The Nth entry in the array is the address of the Nth character string passed as an argument on the spawn(), exec(), or command invocation.

COBOL programs are not recommended as main programs because they will not be portable to other platforms. Instead, use a C main routine and have it call the COBOL programs.
Running under z/OS UNIX

- DISPLAY UPON SYSOUT data is written to stdout unless a DD is allocated that matches the value in the OUTDD compiler option.
- In order to run COBOL programs in more than one thread, all of the COBOL programs have to be compiled with the Enterprise COBOL compiler using the THREAD compiler option.
- The COBOL SORT and MERGE statements are not supported.

For more information about compiling, link-editing, and running COBOL programs in a z/OS UNIX shell environment, see [Enterprise COBOL for z/OS Programming Guide](#) or [COBOL for OS/390 & VM Programming Guide](#).

### Basic Link-Editing and Running PL/I Routines under z/OS UNIX with POSIX(ON)

**Note:** The following sections do not apply to VisualAge PL/I; they only apply to the earlier PL/I products.

When the run-time option POSIX(ON) is specified, PL/I routines in the IPT follow the same rules and behave the same as when POSIX(ON) is not in effect.

PL/I routines in non-IPTs, however, must observe the following rules, or the result is unpredictable. No run-time diagnosis is provided to enforce these rules:

- The non-IPT must be created by a C/C++ routine or assembler program. PL/I routines must be reentrant and in AMODE(31). A PL/I routine can be the first routine in the thread. To ensure the PL/I-specific run-time is available at the time the PL/I routine is running in a non-IPT, one of the following must be true in the main executable program:
  - A PL/I routine directly calls a C/C++ routine
  - A C/C++ routine directly calls a PL/I routine
  - A PL/I for MVS & VM routine is present in the executable program
  - Language Environment PL/I signature CSECT CEESG010 is explicitly included in the executable program

If none of the above exists in the main executable program and a PL/I routine is going to run in a particular thread, you must do one of the following in that thread:

- Fetch or dynamically call an executable program that contains a PL/I routine
- Fetch or dynamically call an executable program that contains Language Environment PL/I signature CSECT CEESG010

- PL/I routines in non-IPTs are supported in the same environments as the C/C++ routines, except the z/OS UNIX shells. The executable form of PL/I routines, however, can run under the shells in conjunction with C/C++ routines in the application using the utilities provided by z/OS UNIX.

- OS PL/I routines can be in non-IPTs. See [Enterprise PL/I for z/OS and OS/390 Migration Guide](#) for the OS PL/I executable programs supported under Language Environment.

- The following functions are not supported:
  - PL/I language constructs associated with MTF, the Language Environment PL/I MTF-specific run-time option PLITASKCOUNT, the Language Environment PL/I MTF-specific trace facility via the run-time option TRACE(ON,,LE=2), and the PL/I MTF-specific data set SIBMTASK. The language constructs are:
    - CALL statement with TASK, EVENT, or PRIORITY option
Running under z/OS UNIX

- EVENT variable
- COMPLETION and STATUS built-in function and pseudovariable
- WAIT statement
- PRIORITY built-in function and pseudovariable
- DELAY statement

- I/O using PL/I language statements is not supported except for the limited support provided using the SYSPRINT file and DISPLAY statement.
- PL/I FETCH and RELEASE statements are not supported.
- Controlled variables are not supported.
- Data sharing among threads is limited. Variables must not be referred to across thread boundaries even though the scope of the PL/I names declaration is unchanged.
- ON-unit inheritance is defined at the thread level. No ON-unit inheritance is provided from the creating threads.

- The following functions are supported with restrictions:
  - SYSPRINT
    If the SYSPRINT file is defined as STREAM OUTPUT EXTERNAL and it is opened in the IPT before any other threads are created, the SYSPRINT file can be shared among the threads. The file must remain open while other threads are using it. The file must be closed explicitly by the IPT or implicitly by Language Environment when the application terminates.
  - DISPLAY
    The DISPLAY statement without the REPLY option and EVENT option is supported.
  - CALL
    The PL/I routine in the non-IPT must not call a subroutine fetched in the initial thread, even if the routine has been fetched before the noninitial thread is created.
  - EXIT
    EXIT is not recommended. When it is used, only the current thread is exited. If the EXIT statement is used in the initial thread, the entire application terminates. There is no defined order as to which thread terminates first.
  - STOP
    STOP is not recommended. When it is used, the entire application terminates. There is no defined order as to which thread terminates first.
  - If a thread is designed to be used many times before it is terminated, reset the user return code by using PLIRETC(0) in the first PL/I routine in the thread.

- The z/OS UNIX-defined signals are handled in the same way for PL/I routines in non-IPT and IPT environments. If the z/OS UNIX signals are delivered to PL/I routines, the signals are ignored until the PL/I routine returns.

Basic Link-Editing and Running PL/I MTF Applications under z/OS UNIX

SIBMTASK is provided to create the main executable program for PL/I MTF applications. SIBMTASK must be concatenated before SCEELKED when the main executable program is created, whether you are creating a new PL/I MTF application or relink-editing an existing OS PL/I routine with Language Environment. SIBMTASK replaces PLITASK under OS PL/I. If the main executable program of your application is link-edited with SIBMTASK or OS PL/I PLITASK, but does not
use multitasking functions, you might notice some performance loss during initialization and termination. The same releases of OS PL/I executable programs are supported by multitasking as well as nonmultitasking applications. The OS PL/I shared library support is the same for both multitasking and nonmultitasking applications.

PL/I multitasking follows the Language Environment program management model discussed in Chapter 13, “Program Management Model,” on page 159. PL/I MTF supports a single Language Environment process within an address space, and is supported in the initial enclave only. If a PL/I multitasking application contains nested enclaves, the initial enclave must contain a single task. Violation of any of these rules is not diagnosed and is likely to cause unpredictable results.

The POSIX(ON) run-time option is not supported for a PL/I MTF application and therefore no programs, including assembler programs, in the application can invoke any POSIX functions. If POSIX(ON) is in effect when a multitasking main executable program is encountered, the application will abend.

For a more detailed discussion of PL/I MTF support, see PL/I for MVS & VM Programming Guide and PL/I for MVS & VM Language Reference. For more information on migration considerations for OS PL/I MTF applications, see Enterprise PL/I for z/OS and OS/390 Migration Guide.
Chapter 8. Using IBM-Supplied Cataloged Procedures

A cataloged procedure is a set of job control statements that are stored in a system library (for example SYS1.PROCLIB). The storage location for cataloged procedures is installation-defined and might differ at your location from what is shown here.

Within a cataloged procedure, there are typically one or more EXEC statements, each of which can be followed by one or more DD statements. You can retrieve a cataloged procedure from the library by using its member name in an EXEC statement of a job control statement in the input stream.

Cataloged procedures can contain statements for the processing of an entire job, or statements to process one or more steps of a job, with the remaining steps defined in job control statements in the input stream. A job can use several cataloged procedures to process one or more of the job steps, or it can use the same cataloged procedure in more than one job step.

You can use cataloged procedures to save time and reduce JCL errors. If the statements in the procedure do not match your requirements exactly, you can easily modify them or add new statements for the duration of a job.

The cataloged procedures shown in this section are intended for use as references and do not necessarily reflect the procedures as they are provided at your installation. If options are not explicitly supplied with the procedure, default options established at the installation apply. You can override these default options by using an EXEC statement that includes the desired options (see “Overriding and Adding to EXEC Statements” on page 114).

Invoking Cataloged Procedures

To invoke a cataloged procedure, specify its name in the PROC parameter of an EXEC statement. You do not need to code the keyword PROC. For example, to use the cataloged procedure CEEWLG, include the following statement in an appropriate position among your other job control statements in the input stream:

//stepname EXEC PROC=CEEWLG

or

//stepname EXEC CEEWLG

Either of these EXEC statements can be used to call the IBM-supplied cataloged procedure CEEWLG to process the job step specified in stepname.

A job that calls for a cataloged procedure to run can also contain DD statements that are applicable to the cataloged procedure, such as:

- Other cataloged procedures to be run
- Other (single or multiple) executions of the same cataloged procedure
- Executable programs to be run

Step Names in Cataloged Procedures

The stepname in a cataloged procedure is the same as the abbreviated processor name. For example, the step that executes a compiled and link-edited program is named GO. In the procedure named CEEWLG (see “CEEWLG — Link and Run a Language Environment-Conforming Non-XPLINK Program” on page 109), the first
IBM-Supplied Cataloged Procedures

Step is named LKED, and the second is named GO. Some of the PROCs provided are for creating constructed reentrant C/C++ executables. See “Making Your C/C++ Program Reentrant” on page 139 for a description of constructed reentrant C/C++ programs.

Some of these PROCs use a prelink step, for when the prelinker must still be used. Some have a P in their names, such as EDCPL, to denote the prelink step PLKED. Other PROCs, for which the prelinker was mandatory when the linkage editor was used (such as CBCCL) have just an L in their names, to denote both the prelink step PLKED and the link-edit step LKED.

PROCs which must use the binder (that is they cannot use the linkage editor), have a B in their names to denote the binder step BIND, such as CBCL. These typically have counterpart PROCs with an L in their names, such as CBCL, which can be used when the linkage editor must be used; these may also use the prelinker, and therefore may or may not have a P in their names.

PROCs which have an L in their names to denote the link-edit step LKED, which do not have a counterpart PROC with a B in their names, do not have a prelink step. These generic link-edit PROCs can be used with the binder, and also will work correctly with the linkage editor. In order for these generic link-edit PROCs to work with constructed reentrant C/C++ programs, the appropriate overrides must be used. See “Modifying Cataloged Procedures” on page 114 for some examples.

Unit Names in Cataloged Procedures

The esoteric unit name used in IBM-supplied cataloged procedures is one of the following:

UNIT=SYSDA
UNIT=VIO

Esoteric unit names are defined during system initialization and installation; the installation should maintain a list of esoteric unit names. Both these names may be defined as VIO (virtual I/O) data sets. See z/OS MVS JCL User’s Guide for more information about VIO data sets.

All of the data sets which may be created use one of these esoteric units names. Most of these are set up as temporary data sets, and some are typically overridden to become permanent data sets, by using procedure parameters, or by overriding procedure statements. See “Modifying Cataloged Procedures” on page 114 for more information on overriding statements in cataloged procedures.

Data Set Names in Cataloged Procedures

When you use DSNAMEx="name in a DD statement, it is a temporary data set that is deleted when the job terminates. If you want the data set to be kept, override the DD statement with a permanent data set name and specify the appropriate DISP parameters.

See “Required DD Statements” under “Writing JCL for the Link-Edit Process” on page 72 for a detailed description of each of the data sets included in the cataloged procedures discussed in this chapter. See “Overriding and Adding to EXEC Statements” on page 114 for instructions about overriding DD statements in cataloged procedures.
### IBM-Supplied Cataloged Procedures

The IBM-supplied cataloged procedures that you can use under Language Environment are listed in Table 15.

The following sections provide further details on, and example invocations of, the language-independent cataloged procedures CEEWG, CEEWL, CEEWLG, CEEXR, CEEXL and CEEEXLR.

**CEEWG — Load and Run a Language Environment-Conforming Non-XPLINK Program**

The CEEWG cataloged procedure shown in Figure 39 on page 108 includes the GO step, which loads an object module produced by the compiler and executes the load module.

The following DD statement, indicating the location of the object module, must be supplied in the input stream to the GO step:

```
//GO.SYSIN DD *  (or appropriate parameters)
```
The data set SCEELKED must be included in your link-edit SYSLIB concatenation. This is the name of the Language Environment resident library. (The high-level qualifier of this resident library might have been changed at your installation.)

The data set SCEERUN must be included in the STEPLIB DD statement for the GO step. (The name of this load library might have been changed at your installation.)

If the application refers to any data sets in the execution step (such as user-defined files or SYSIN), DD statements that define these data sets must be provided.

```
//CEEWG PROC LIBPRFX='CEE'
//GO EXEC PGM=LOADER,REGION=2048K
//SYSLIB DD DSNAM=&LIBPRFX..SCEELKED,DISP=SHR
//SYSLOUT DD SYSPRINT DD SYSOUT**
//SYSLIB DD DDNAME=SYSIN
//SYSLIB DD DSNAM=&LIBPRFX..SCEERUN,DISP=SHR
//SYSPRINT DD SYSPRINT DD SYSOUT**
//CEEEDUMP DD SYSPRINT DD SYSOUT**
//SYSUDUMP DD SYSPRINT DD SYSOUT**
```

*Figure 39. Cataloged Procedure CEEWG, Which Loads and Runs a Program Written in Any Language Environment-Conforming HLL*

**CEEWL — Link a Language Environment-Conforming Non-XPLINK Program**

The CEEWL cataloged procedure shown in Figure 40 includes the LKED step that invokes the binder (symbolic name HEWL) to link-edit an object module.

The following DD statement, indicating the location of the object module, must be supplied in the input stream:

```
//LKED.SYSIN DD * (or appropriate parameters)
```

The data set SCEELKED must be included in your link-edit SYSLIB concatenation. This is the name of the Language Environment link-edit library. (The high-level qualifier of this link-edit library might have been changed at your installation.)

```
//CEEWL PROC LIBPRFX='CEE',
//LKED EXEC PGM=HEWL,REGION=1024K
//SYSLIB DD DSNAM=&LIBPRFX..SCEELKED,DISP=SHR
//SYSPRINT DD SYSPRINT DD SYSOUT**
//SYSLIB DD DDNAME=SYSIN
//SYSLMOD DD DSNAM=&PGMLIB(&GOPGM),
//   SPACE=(TRK,(10,10,1))
//   UNIT=SYSDA,DISP=(MOD,PASS)
//SYSUT1 DD UNIT=SYSDA,SPACE=(TRK,(10,10))
```

*Figure 40. Cataloged Procedure CEEWL, Which Link-Edits a Program Written in Any Language Environment-Conforming HLL*
CEEWLG — Link and Run a Language Environment-Conforming Non-XPLINK Program

The CEEWLG cataloged procedure in Figure 41 includes the LKED step, which invokes the binder (symbolic name HEWL) to link-edit an object module, and the GO step, which executes the executable program produced in the first step.

The following DD statement, indicating the location of the object module, must be supplied in the input stream:

//LKED.SYSIN DD * (or appropriate parameters)

The data set SCEELKED must be included in your link-edit SYSLIB concatenation. This is the name of the Language Environment link-edit library. (The high-level qualifier of this link-edit library might have been changed at your installation.)

The data set SCEERUN must be included in the STEPLIB DD statement for the GO step. (The name of this load library might have been changed at your installation.)

If the application refers to any data sets in the execution step (such as user-defined files or SYSIN), you must also provide DD statements that define these data sets.

```
//CEEWLG    PROC  LIBPRFX='CEE',GOPGM=GO
//LKED      EXEC  PGM=HEWL,REGION=1024K
//SYSLIB    DD    DSNAME=&LIBPRFX..SCEELKED,DISP=SHR
//SYSPRINT  DD    SYSOUT**
//SYSLIN    DD    DDNAME=SYSIN
//SYSLMOD   DD    DSNAME=&GOSET(&GOPGM),SPACE=(TRK,(10,10,1)),
//               UNIT=SYSDA,DISP=(MOD,PASS)
//SYSUT1    DD    UNIT=SYSDA,SPACE=(TRK,(10,10))
//GO        EXEC  PGM=*.LKED.SYSLMOD,COND=(4,LT,LKED),REGION=2048K
//STEPLIB   DD    DSNAME=&LIBPRFX..SCEERUN,DISP=SHR
//SYSPRINT  DD    SYSOUT**
//CEEDUMP   DD    SYSOUT**
//SYSUDUMP  DD    SYSOUT**
```

Figure 41. Cataloged Procedure CEEWLG, Which Link-Edits and Runs a Program Written in Any Language Environment-Conforming HLL

CEEXR — Load and Run a Language Environment-Conforming XPLINK Program

The CEEXR cataloged procedure shown in Figure 42 on page 110 includes the GO step, which loads and executes an XPLINK program module specified on input parameters to the procedure.

The data sets SCEERUN and SCEERUN2 must be included in the STEPLIB DD statement for the GO step. (The high-level qualifier of these load libraries might have been changed at your installation.)

If the application refers to any data sets in the execution step (such as user-defined files), DD statements that define these data sets must be provided.
CEEXL — Link-Edit a Language Environment-Conforming XPLINK Program

The CEEXL cataloged procedure shown in Figure 43 includes the LKED step that invokes the Binder (symbolic name IEWL) to link-edit an object module specified on input parameters to the procedure.

Any side-decks necessary to resolve references in this object module to DLLs must be specified on a SYSIMP DD statement.

The data set SCEEBIND must be included in your link-edit SYSLIB concatenation. This is the name of the Language Environment link-edit library for XPLINK applications. (The high-level qualifier of this link-edit library might have been changed at your installation.)

```
//CEEXL PROC INFILE=, < INPUT ... REQUIRED
// LIBPRFX='CEE', < PREFIX FOR LIBRARY DSN
// LREGSIZ='20M', < BINDER REGION SIZE
// LPARMS='MAP, LIST=NOIMP', < ADDITIONAL BINDER PARM
// OUTFILE='&&GSET(GO),DISP=(NEW,PASS),UNIT=SYSALLDA,SPACE=(TRK,(7,7,
// 1)),DSNTYPE=LIBRARY'
//LKED EXEC PGM=IEWL,REGION=&LREGSIZ,
// PARM='AMODE=31,RENT,DYNAM=DLL,CASE=MIXED,&LPARMS'
//SYSLIB DD DSNAME=&LIBPRFX..SCEEBIND,DISP=SHR
//SYSPRINT DD SYOUT**
//SYSLIB DD DSNAME=&INFILE,DISP=SHR
// SYSDUMP DD DUMMY
//SYSLMOD DD DSNAME=&OUTFILE
//SYSLMOD DD DSNAME=SYSIN
//SYSLMOD DD DUMMY

Figure 43. Cataloged Procedure CEEXL, Which Link-Edits a Program Compiled XPLINK
```
CEEXLR — Link and Run a Language Environment-Conforming XPLINK Program

The CEEXLR cataloged procedure shown in Figure 44 includes the LKED step, which invokes the Binder (symbolic name IEWL) to link-edit an object module, and the GO step, which executes the program module produced in the first step.

Any side-decks necessary to resolve references in this object module to DLLs must be specified on a SYSIMP DD statement.

The data set SCEEBIND must be included in your link-edit SYSLIB concatenation. This is the name of the Language Environment link-edit library for XPLINK applications. (The high-level qualifier of this link-edit library might have been changed at your installation.)

The data sets SCEERUN and SCEERUN2 must be included in the STEPLIB DD statement for the GO step. (The high-level qualifier of these load libraries might have been changed at your installation.)

If the application refers to any data sets in the execution step (such as user-defined files or SYSIN), DD statements that define these data sets must be provided.

```plaintext
//CEEXLR PROC INFILE=,< INPUT ... REQUIRED
//   LIBPRFX='CEE',< PREFIX FOR LIBRARY DSN
//   LREGSIZ='20M',< BINDER REGION SIZE
//   LPARMS='MAP, LIST=NOIMP',< ADDITIONAL BINDER PARMS
//   GREGSIZ='2048K',< EXECUTION REGION SIZE
//   GPARMS='XPLINK(ON), TERMTHDACT(UADUMP)/',< RUN-TIME OPTS
//   OUTFILE='&&GSET(GO), DISP=(NEW, PASS), UNIT=SYSALLDA, SPACE=(TRK,(7,7,
//   ))', DSNTYPE=LIBRARY'
//LKED EXEC PGM=IEWL, REGION=&LREGSIZ,
//   PARM='AMODE=31, RENT, DYNAM=DLL, CASE=MIXED, &LPARMS'
//SYSLIB DD DSNNAME=&LIBPRFX..SCEEBIND, DISP=SHR
//SYSLIB DD DSNNAME=&LIBPRFX..SCEELIB(CELHS003), DISP=SHR
//SYSLIB DD DSNNAME=&LIBPRFX..SCEELIB(CELHS001), DISP=SHR
//DD DSNNAME=SYSIN
//SYSLMOD DD DSNNAME=&OUTFILE
//SYSUT1 DD UNIT=SYSALLDA, SPACE=(TRK,(10,10))
//SYSLMOD DD DUMMY
//GO EXEC PGM=*.LKED.SYSLMOD, COND=(4, LT, LKED), REGION=&GREGSIZ,
//   PARM='&GPARMS'
//STEPLIB DD DSNNAME=&LIBPRFX..SCEERUN, DISP=SHR
//   DSNNAME=&LIBPRFX..SCEERUN2, DISP=SHR
//SYSLIB DD DSNNAME=&LIBPRFX..SCEEBIND, DISP=SHR
//SYSLIB DD DSNNAME=&LIBPRFX..SCEELIB(CELHS003), DISP=SHR
//SYSLIB DD DSNNAME=&LIBPRFX..SCEELIB(CELHS001), DISP=SHR
//DD DSNNAME=SYSIN
```

Figure 44. Cataloged Procedure CEEXLR, Which Link-Edits and Runs a Program Compiled XPLINK

AFHWL — Link a Program Written in Fortran

The AFHWL cataloged procedure shown in Figure 45 on page 112 includes the LKED step, which invokes the binder (symbolic name HEWL) to link-edit an object module. The procedure can be used to link-edit applications containing Fortran or
assembler routines having names that conflict with existing C library routines, as discussed in "Resolving Library Module Name Conflicts between Fortran and C" on page 17.

The following DD statement, indicating the location of the object module, must be supplied in the input stream:

//LKED.SYSIN DD * (or appropriate parameters)

The data sets SAFHFORT and SCEELKED must both be included in your link-edit SYSLIB concatenation (in that order). SAFHFORT is the name of the Fortran-specific link-edit library and is used to resolve certain Fortran intrinsic function names. SCEELKED is the name of the Language Environment link-edit library. (The high-level qualifier of this link-edit library might have been changed at your installation.)

The data set SCEERUN must also be included in the STEPLIB DD statement for the GO step. (The name of the load library might have been changed at your installation.)

Figure 45. Using AFHWL to Link a Program Written in Fortran

AFHWL — Link and Run a Program Written in Fortran

The AFHWL cataloged procedure shown in Figure 46 on page 113 includes the LKED step, which invokes the binder (symbolic name HEWL) to link-edit an object module, and the GO step, which executes the executable program produced in the first step. The procedure can be used to link-edit and run applications containing Fortran or assembler routines having names that conflict with existing C library routines, as discussed in "Resolving Library Module Name Conflicts between Fortran and C" on page 17.

The following DD statement, indicating the location of the object module, must be supplied in the input stream:

//LKED.SYSIN DD * (or appropriate parameters)

The data sets SAFHFORT and SCEELKED must both be included in your link-edit SYSLIB concatenation (in that order). SAFHFORT is the name of the Fortran-specific link-edit library and is used to resolve certain Fortran intrinsic function names. SCEELKED is the name of the Language Environment link-edit library. (The high-level qualifier of this link-edit library might have been changed at your installation.)

The data set SCEERUN must also be included in the STEPLIB DD statement for the GO step. (The name of the load library might have been changed at your installation.)
If the application refers to any data sets in the execution step (such as user-defined files or SYSIN), you must also provide DD statements that define these data sets.

If the application refers to any data sets in the execution step (such as user-defined files or SYSIN), you must also provide DD statements that define these data sets.

AFHWN — Resolving Name Conflicts between C and Fortran

The AFHWN cataloged procedure shown in Figure 47 includes the LKED step, which invokes the binder (symbolic name HEWL) to link-edit an object module.

The following DD statement, indicating the location of the object module, must be supplied in the input stream:

//LKED.SYSIN DD *  (or appropriate parameters)

The contents of the SYSIN data set must include the CHANGE statements in member AFHWNCH in SCEESAMP and the object module itself. See "Resolving Library Module Name Conflicts between Fortran and C" on page 17 for further details.

The data sets SAFHFORT and SCEELKED must both be included in your link-edit SYSLIB concatenation (in that order). SAFHFORT is the name of the Fortran-specific link-edit library and is used to resolve certain Fortran intrinsic function names. SCEELKED is the name of the Language Environment link-edit library. The high-level qualifier of this link-edit library might have been changed at your installation. Figure 47 shows the LKED in AFHWN.

AFHWN PROC Libprfx='CEE', PgmName='&pgmlib', GOPgm='GO'

//LKED EXEC PGM=HEWL,REGION=1024K, PARM='NCAL,LET'
//SYSLIB DD DSNAME=&LIBPRFX..SAFHFORT,DISP=SHR

Figure 47. Cataloged Procedure AFHWN, Used in Resolving Name Conflicts

Chapter 8. Using IBM-Supplied Cataloged Procedures  113
IBM-Supplied Cataloged Procedures

Modifying Cataloged Procedures

You can modify the statements of a cataloged procedure for the duration of the job step in which it is invoked, either by overriding one or more parameters in the EXEC or DD statements or by adding DD statements to the procedure. Any parameter in a cataloged procedure, except the PGM=progname parameter in the EXEC statement, can be overridden. Parameters or statements not specified in the procedure can also be added. When a cataloged procedure is overridden or added to, the changes apply only during one execution. The changes do not affect the master copy of the cataloged procedure stored in the procedure library.

The following sections discuss overriding and adding to EXEC and DD statements, respectively. For complete details, see z/OS MVS JCL Reference.

Overriding and Adding to EXEC Statements

A parameter with a qualified name (qualified by the procedure step in which it is specified) applies only to the EXEC statement in which it is specified. If a parameter of an EXEC statement that invokes a cataloged procedure has an unqualified name, the parameter applies to all the EXEC statements in the cataloged procedure. For example, REGION=2048 specifies a region size of 2048 for all of the EXEC statements in a given procedure, whereas REGION=G0=2048 applies to only the GO step of the procedure.

If you want to modify a multiple step procedure, you can do so by specifying parameters with qualified names on a step-by-step basis. If you want to modify the entire procedure, specify the name of the parameter in an EXEC statement without qualifying it. The modifications override existing parameters in the cataloged procedure.

Overriding and Adding DD Statements

You can override or add a DD statement by specifying a DD statement whose name is composed of the ddbname of the DD statement being overridden, preceded by the procedure stepname that qualifies that ddbname:

//proccstep.ddname DD {appropriate parms}

You must observe the following when overriding or adding a DD statement within a step in a procedure:

- Overriding DD statements must be in the same order in the input stream as they are in the cataloged procedure.
- DD statements to be added must follow overriding DD statements.

Additionally, you should be aware of the following when overriding a DD statement:

- To nullify a keyword parameter (except the DCB and AMP parameters), write the keyword and an equal sign followed by a comma in the overriding DD statement. For example, to nullify the use of the UNIT parameter, specify UNIT=, in the overriding DD statement.
- You can nullify a parameter by specifying a mutually exclusive parameter. For example, you can nullify the SPACE parameter by specifying the mutually exclusive SPLIT parameter in the overriding DD statement.
- There is no order of precedence for the parameters. Their placement (order of execution) does not matter.
- To override DD statements in a concatenation of data sets, you must provide one DD statement for each data set in the concatenation. Only the first DD statement
in the concatenation should be named. If the DD statement you want to change or add follows one or more DD statements that will be unchanged, code one DD statement with blank operand for each unchanged DD statement ahead of the first DD statement that you want to change or add.

For example, to add your load module data set, MY.LIB, to the run-time STEPLIB in a Language Environment cataloged procedure containing one data set whose DD statement you do not want to change, code:

```language-plaintext
//GO.STEPLIB DD
//   DSN=MY.LIB,DISP=SHR
```

This causes your load module data set to be searched after the data set named in the STEPLIB DD statement in the cataloged procedure.

To have another data set searched before any data sets already in the cataloged procedure, you must specify all the data sets in your overriding DD statements. For example, to have CEE.SIBMMATH searched before CEE.SCEELKED (assuming it is a non-XPLINK application), code:

```language-plaintext
//LKED.SYSLIB DD
//   DSN=CEE.SIBMMATH,DISP=SHR
//   DSN=CEE.SCEELKED,DISP=SHR
```

This causes the PL/I versions of the math routines to be link-edited into your load module rather than the identically named SCEELKED math routines.

- If the DDNAME=ddname parameter is specified in a cataloged procedure, it cannot be overridden; rather, it can refer to a DD statement supplied at the time of execution.

The example in Figure 48 shows how to override parameters in a cataloged procedure by:

- Changing the library prefix for the SCEELKED link library to SYS1
- Increasing the region for linking and running the application
- Passing the RPTSTG and RPTOPTS options to the load module when it is executed in the GO step of the procedure
- Specifying PROGRAM1 in USER.OBJLIB as the input object module to the binder

```language-plaintext
//CEEWLG JOB
//*/
//LINKGO EXEC CEEWLG,
//   LIBPRFX='SYS1',
//   REGION=2048K,
//   PARM.GO='RPTSTG(ON) RPTOPTS(ON)/'
//*/
//LKED.SYSLIB DD DSN=USER.OBJLIB(PROGRAM1),DISP=SHR
//*/
```

Figure 48. Overriding Parameters in the CEEWLG Cataloged Procedure

**Overriding Generic Link-Edit Procedures for Constructed Reentrant Programs**

To use generic link-edit procedures (as described in Step Names in Cataloged Procedures on page 103), both the EXEC statement parameters and DD statements may need to be overridden.

The following are some examples of how to invoke the CEEWL PROC.
1. Creating a C executable which may be constructed reentrant:
   - Parameter COMPAT(CURRENT) assures the highest level of program object will be produced.
   - SCEELKEX allows direct resolution of C/C++ language function names.
   - DSNTYPE=LIBRARY assures that the output data set will be a PDSE (rather than a PDS). STORCLAS may also have to be specified for a new SMS managed data set.
   - Object module USER.OBJ(PROGRAM1) is input.

   //CEEWL JOB
   //*
   //SETLIB SET LIBPRFX=CEE
   //SETUSER SET USER=USER1
   //*
   //LINK EXEC CEEWL,
   // LIBPRFX=LIBPRFX.,
   // PARM.LKED='COMPAT(CURRENT)'
   //LKED.SYSLIB DD DSN=&LIBPRFX..SCEELKEX,DISP=SHR
   // DD DSN=&LIBPRFX..SCEELKED,DISP=SHR
   //LKED.SYSLMOD DD DSNTYPE=LIBRARY
   //*
   //LKED.SYSIN DD DSN=&USER.OBJ(PROGRAM1),DISP=SHR
   //*

2. Create a C DLL, which can also be used as an autocall library. In addition to the previous example:
   - DYNAM(DLL) causes the import and export information to be created and stored in the executable.
   - ALIASES(ALL) causes hidden aliases to be created for all external functions and variables, for subsequent use as an autocall library.
   - Program object USER.LOADLIB(CDLL) is output.
   - Definition side-deck USER.EXP(CDLL) is output (it contains IMPORT statements for all exported symbols).

   //CEEWL JOB
   //*
   //SETLIB SET LIBPRFX=CEE
   //SETUSER SET USER=USER1
   //*
   //LINK EXEC CEEWL,
   // PARM.LKED='COMPAT(CURR),DYNAM(DLL),ALIASES(ALL)'
   //LKED.SYSLIB DD DSN=&LIBPRFX..SCEELKEX,DISP=SHR
   // DD DSN=&LIBPRFX..SCEELKED,DISP=SHR
   //LKED.SYSLMOD DD DSN=&USER.LOADLIB(CDLL),DISP=SHR,
   // DSNTYPE=LIBRARY
   //LKED.SYSGlobal DD DSN=&USER.EXP(CDLL),DISP=SHR
   //*
   //LKED.SYSIN DD DSN=&USER.OBJ(PROGRAM1),DISP=SHR
   //*
Chapter 9. Using Run-Time Options

This chapter shows you how to specify run-time options as installation defaults, application defaults, in MVS JCL, in commands, in assembler exits, or in your source code. For more information about how Language Environment run-time options map to specific HLL options, see z/OS Language Environment Programming Reference.

Understanding the Basics

Language Environment provides run-time options with which you can control certain aspects of your program’s processing. You can set the default values for most of these options at installation time. See z/OS Language Environment Programming Reference for syntax and detailed information on the use of Language Environment run-time options.

Specifying Run-Time Options

You can specify Language Environment run-time options in the following ways:

As installation defaults

The CEEDOPT assembler language source file establishes installation defaults using the CEEXOPT macro. The file initially contains IBM-supplied default values for each of the Language Environment run-time options. The syntax for CEEXOPT is presented in the section, “CEEXOPT Invocation Syntax” on page 124. During installation of Language Environment, the default values contained in the CEEDOPT source file can be edited and assembled to create the CEEDOPT object module. All applications that run in the common run-time environment operate using these default values for the run-time options. The CEEDOPT object module resides in the SCEERUN load library.

It is possible to associate a nonoverrideable attribute with each individual run-time option. Each option in CEEDOPT must be specified as either overrideable (OVR) or nonoverrideable (NONOVR). This allows the installation to enforce options that are critical to the overall Language Environment operating environment.

Language Environment also provides the CEEOPT source program to establish installation defaults for run-time options under CICS. See below for the method to specify run-time options for a particular CICS region.

For more information on specifying options at installation, see z/OS Program Directory.

As region-wide defaults applied to a CICS or IMS region

The CEEROPT assembler language source file establishes region-wide defaults using the CEEXOPT macro. The file initially contains IBM-supplied default values for each of the Language Environment run-time options. The syntax for CEEXOPT is presented in the section, “CEEXOPT Invocation Syntax” on page 124. At any time, the default values contained in the CEEROPT source file can be edited and assembled to create the CEEROPT stand-alone load module. All transactions that run in the CICS region or IMS region that use Language Environment Library Routine Retention, operate using these default values for the run-time options. The CEEROPT module resides in a user-specified load library.
Using Run-Time Options

It is possible to associate a nonoverrideable attribute with each individual run-time option. Each option in CEEROPT must be specified as either overrideable (OVR) or nonoverrideable (NONOVR). This allows the region to enforce options that are critical to the operation of the region. CEEROPT should not specify OVR for a run-time option which is defined as NONOVR in the installation-wide defaults, as this will be ignored and a warning message will be issued.

CEEROPT is optional. If it is used, you should code just the run-time options to be changed from the defaults specified in CEECOPT and CEEDOPT for use in a particular region. Run-time options which are omitted from CEEROPT will remain the same as the installation defaults in CEEOPT and CEEDOPT.

In the CLER CICS transaction

The CICS transaction (CLER) allows you to display all the current Language Environment run-time options for a region, and to also have the capability to modify a subset of these options.

The following run-time options can be modified with the CLER transaction:

- TRAP(ON|OFF)
- TERMTHDACT(QUIET|IMSG|TRACE|IDUMPM|UAONLY|UATRACE|UADUMP|UAIMM)
- RPTOPTS(ON|OFF)
- RPTSTG(ON|OFF)
- ALL31(ON|OFF)
- CBLPSHPOP(ON|OFF)

Note that setting RPTOPTS(ON) or RPTSTG(ON) in a production environment can significantly degrade performance. Also, if ALL31(OFF) is set in a production environment, the stack location will be set to BELOW the 16 MB line, which could cause the CICS region to abend due to lack of storage.

The LAST WHERE SET column of the Language Environment run-time options report will contain CICS CLER Trans for those options that were set by CLER.

As application defaults

The CEEUOPT assembler language source program sets application defaults using the CEEXOPT macro. CEEUOPT can be edited and assembled to create an object module, CEEUOPT, that can be linked with an application.

As noted previously, CEEDOPT establishes installation defaults and CEEROPT establishes region-wide defaults using the CEEXOPT macro. When the program runs, the options specified in CEEUOPT override any corresponding overrideable CEEDOPT or CEEROPT options.

CEEOPT must be linked with your application to establish application defaults.

In the assembler user exit

See "CEEBXITA Assembler User Exit Interface" on page 463 for information about how to specify a list of run-time options in the assembler user exit.

In the storage tuning user exit

The storage tuning user exit can be used to set the Language Environment
storage options STACK, LIBSTACK, HEAP, ANYHEAP, and BELOWHEAP. See \textit{z/OS Language Environment Customization} for information on the storage tuning user exit.

\textbf{Note:} Vendor Heap Manager activity will not be handled by the Language Environment storage tuning user exit.

\textbf{In TSO/E commands, on application invocation} 
You can specify run-time options as options on the \texttt{CALL} command. See "Running your application under TSO/E" on page 91 for more information.

\textbf{In C applications invoked by one of the exec family of functions} 
You can specify the values of run-time options by using the \texttt{CEE_RUNOPTS} environment variable. For more information, see "Using \texttt{CEE_RUNOPTS} to Specify Run-Time Options" on page 122.

\textbf{As JCL} 
You can specify run-time options in the PARM parameter of the JCL EXEC statement. See "Specifying Run-Time Options in the EXEC Statement" on page 70 for details.

\textbf{In your source code:} 

\textbf{C and C++} 
C provides the \texttt{#pragma runopts} directive, with which you can specify run-time options in your source code.

You must specify \texttt{#pragma runopts} in the source file that contains your main function, before the first C statement. Only comments and other pragmas can precede \texttt{#pragma runopts}.

Specify \texttt{#pragma runopts} as follows:

\begin{verbatim}
Syntax

#pragma runopts(\ldots option \ldots)

option is a Language Environment run-time option.

For C++ applications, the following values are not allowed for compilation:
\begin{itemize}
  \item PLIST(xxx)
  \item ENV(xxx)
  \item NOEXECOPS
  \item NOREDIR
  \item NOARGPARSE
\end{itemize}

You must use the corresponding C++ compiler options.

For more information about using C/C++ pragmas, see \textit{z/OS C/C++ User's Guide}.

\textbf{PL/I} 
Run-time options can be specified in a PL/I source application by means of the following declaration:
Using Run-Time Options

DCL PLIXOPT CHAR(length) VAR INIT('string')
STATIC EXTERNAL;

where string is a list of options separated by commas or blanks, and length is a constant equal to or greater than the length of string. Run-time options in PLIXOPT are parsed by the compiler. For VisualAge PL/I and PL/I for MVS & VM, the compilers produce the CEEUOPT CSECT for the PLIXOPT string.

If more than one external procedure in a job declares PLIXOPT as STATIC EXTERNAL, only the first link-edited string is available at run time.

If the PLIXOPT string is specified in an OS PL/I main procedure, the options in the string are processed as if specified in the CEEUOPT CSECT. However, mixing a user-provided CEEUOPT with PLIXOPT is not recommended.

Each time a PL/I application runs, the default run-time options established at installation time apply unless overridden by a PLIXOPT string in the source program or in the PARM parameter of the EXEC statement. Options specified in the PARM parameter override those specified in the PLIXOPT string.

Order of Precedence

It is possible for all the methods listed above to be used for a given application. The order of precedence (from highest to lowest) between option specification methods is:

1. Options defined at installation time that have the nonoverridable (NONOVR) attribute.
2. Storage-related options which are set in the storage tuning user exit.
3. Options specified by the assembler user exit (CEEBXITA).
4. Options specified on invocation of the application (or in the case of an application invoked by one of the exec family of functions, options specified in the environment variable _CEE_RUNOPTS).
5. Options specified within the source program or options specified in CEEUOPT and link-edited with the application. If both types of options have been specified, precedence is determined by the following:
   a. If the application consists of only one HLL (high-level language), the first object module input to the linkage editor (binder) controls which type of option is used by the application.
      For example, suppose that two HLL object modules containing options specified in the source code and that CEEUOPT are input to the linkage editor. If one of the HLL object modules is input to the linkage editor first, the options contained in the second HLL object module and in CEEUOPT are ignored. On the other hand, if CEEUOPT is input first, the options in both HLL object modules are ignored.
   b. If the application consists of only one HLL, and CEEUOPT is not present, the options specified in the first HLL object module input to the linkage editor take precedence, and all other options specified in other object modules are ignored.
   c. If the application consists of multiple HLL object modules, both CEEUOPT (if present) and any options specified in any object module are ignored.
In cases 5a on page 120 and 5b on page 120, the order in which the linkage editor processes object modules is very important. Make sure you fully understand this process.

You can use linkage editor control statements to force the order in which the object modules are input.

6. Region-wide CICS or IMS default options defined within CEEROPT.

7. Option defaults defined at installation time.

Specifying Suboptions in Run-Time Options

Use commas to separate suboptions of run-time options. If you do not specify a suboption, you must still specify the comma to indicate its omission, for example \texttt{STACK(,ANYWHERE,FREE)}. However, trailing commas are not required; \texttt{STACK(4K,4K,ANYWHERE)} is valid. If you do not specify any suboptions, either of the following is valid: \texttt{STACK} or \texttt{STACK()}.  

Specifying Run-Time Options and Program Arguments

To distinguish run-time options from program arguments that are passed to Language Environment, the options and program arguments are separated by a slash (/). (For more information on program arguments, see “Argument Lists and Parameter Lists” on page 132.)

Run-time options usually precede program arguments whenever they are specified in JCL or on application invocation. The possible combinations are described in Table 16. You can override this format to ensure compatibility with COBOL applications. See “COBOL Compatibility Considerations” on page 122 for more information.

<table>
<thead>
<tr>
<th>When...</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>Only run-time options are present</td>
<td>run-time options/</td>
</tr>
<tr>
<td>Only program arguments are present</td>
<td></td>
</tr>
<tr>
<td>1. If a slash is present in the arguments, a preceding slash is mandatory.</td>
<td>One of the following:</td>
</tr>
<tr>
<td>2. If a slash is not present in the arguments, a preceding slash is optional.</td>
<td>1. /program arguments</td>
</tr>
<tr>
<td></td>
<td>2. program arguments</td>
</tr>
<tr>
<td></td>
<td>or</td>
</tr>
<tr>
<td></td>
<td>/program arguments</td>
</tr>
<tr>
<td>Both run-time options and program arguments are present</td>
<td>run-time options/program arguments</td>
</tr>
</tbody>
</table>

You can use the callable service CEE3PRM to retrieve program arguments (for more information, see “z/OS Language Environment Programming Reference”).

In the following example, an object module called MYPROG is created and run using the cataloged procedure CEEWLG. The code in the example overrides the Language Environment defaults for the RPTOPTS and MSGFILE run-time options.

```plaintext
//CEEWLG JOB /*
//LINKG EXEC CEEWLG, // PARAM.GO='RPTOPTS(ON),MSGFILE(OPTRPRT) '/' /*
//LKED.SYSIN DD DSN='userid.MYLIB.OBJLIB(MYPROG)',...DISP=SHR //GO.OPTRPRT DD SYSOUT=A /*
```
Using Run-Time Options

Using _CEE_RUNOPTS to Specify Run-Time Options
If you run C applications that are invoked by one of the exec family of functions, you can use the environment variable _CEE_RUNOPTS to specify invocation Language Environment run-time options. For more information on using the environment variable _CEE_RUNOPTS, see [z/OS C/C++ Programming Guide](https://www.ibm.com/support/docview.zhtml?docid=com.ibm.ZLinuxCAndCPlusPlusV1r6.doc%2FzCPlusPlusV1r6.html).

C and C++ Compatibility Considerations
C provides the #pragma runopts directive for you to specify run-time options in your source code. When #pragma runopts(execops) is in effect (the default), you can pass run-time options from the command line. Run-time options must be followed by a slash (/).

If the main routine is C and #pragma runopts(noexecops) is specified in the source, you cannot enter run-time options on the command line. Language Environment interprets the entire string on the command line including run-time options, if present, as program arguments to the main routine.

For C++ application, the following values are not allowed for compilation:
- PLIST(xxx)
- ENV(xxx)
- NOEXECOPS
- NOREDIR
- NOARGPARSE

You must use C++ compiler options to achieve the same effect achieved using C run-time options.

COBOL Compatibility Considerations
With OS/VS COBOL and VS COBOL II, you must use the following format when specifying the run-time options list:

```
program arguments / run-time options
```

This format is the opposite of the Language Environment-defined format. To ensure compatibility with COBOL, Language Environment provides the run-time option CBLOPTS, which permits you to choose if run-time options or program arguments are expected first in the parameter list. CBLOPTS can only be specified in the user options CSECT, CEEUOPT, or in the installation default run-time options CSECTs, CEEDOPT or CEEROPT. You can specify a slash (/) as part of the program arguments with CBLOPTS(ON) or CBLOPTS(OFF).

CBLOPTS(ON) allows the existing COBOL format of the invocation character string to continue working (program arguments followed by run-time options). When CBLOPTS(ON) is specified, the last slash in a string delineates the program arguments from the run-time options. Anything before the last slash is interpreted as a program argument.

If there are only invalid run-time options, then the entire string is interpreted as a program argument. For example, if you pass the string 11/16/1967, 1967 is interpreted as an invalid run-time option. Since there are no other run-time options, the entire string will be interpreted as a program argument.
Conversely, when CBLOPTS(OFF) is specified, the first slash delineates the run-time options from the program arguments. Anything after the first slash is interpreted as a program argument. CBLOPTS is honored only when a COBOL program is the main routine in the application. For example, if the main routine is C, Language Environment does not honor CBLOPTS. See z/OS Language Environment Programming Reference for more information.

For non-CICS, ensure that COBOL transactions are not link-edited with IGZETUN, which is not supported and which causes an informational message to be logged.

For CICS, ensure that COBOL transactions are not link-edited with IGZEOPT and IGZETUN, which are not supported and which cause an informational message to be logged.

Logging this message for each application inhibits performance.

**Fortran Compatibility Considerations**

Under VS FORTRAN Version 2, a slash (/) is not required after run-time options if only run-time options are passed. With Language Environment, however, a slash following run-time options is mandatory. Therefore, you must check your invocation string to ensure the presence of a slash after the run-time options.

There are some differences between Fortran and Language Environment run-time options. While most of these differences are automatically mapped, some options need to be coded in a different format under Language Environment. In addition, there are other Fortran run-time options that are not available under Language Environment. See z/OS Language Environment Programming Reference for the mapping of Fortran to Language Environment run-time options.

If the run-time options string includes an unrecognized option or suboption, Language Environment prints an informational message to help you identify the source of the error.

You can use the Fortran ARGSTR subroutine to retrieve any user-supplied program arguments from the command line. ARGSTR can be used from your Fortran program to identify the program arguments that were given when the enclave was invoked. For information about using ARGSTR in a Fortran program, see VS FORTRAN Version 2 Language and Library Reference.

**PL/I Compatibility Considerations**

Under OS PL/I, a slash (/) is not required after run-time options if the run-time options are the only ones passed. With Language Environment, however, a slash is mandatory. Therefore, you must check your invocation string to ensure the presence of a slash after the run-time options.

If a PL/I main program is compiled with the NOEXECOPS option, run-time options cannot be specified in the MVS PARM statement. If run-time options are specified, they are passed as program arguments. The effect of the NOEXECOPS option is described in Appendix D, “Operating System and Subsystem Parameter List Formats,” on page 593.
Using Run-Time Options

IMS Compatibility Considerations

You cannot pass run-time options as CEETDLI arguments, nor can you alter the settings of run-time options when invoking IMS facilities. See "Using the Interface between Language Environment and IMS" on page 451 for more information about using the CEETDLI interface.

CEEXOPT Invocation Syntax

Use the CEEXOPT macro to establish installation and programmer default options.

- When invoked during the assembly of the CEEDOPT source program at installation time, CEEXOPT creates the CEEDOPT object module, which establishes installation default options. Language Environment run-time options (except those that are C-specific) must be specified in CEEDOPT. Each option in CEEDOPT must be designated as either overrideable (OVR) or nonoverrideable (NONOVR). In addition, a valid value must be specified for each suboption of each run-time option.

- The CEEXOPT macro also creates the CEEROPT object module when CEEROPT is assembled. CEEROPT can then be linked as a stand-alone module to establish CICS or IMS region-wide run-time options. Since it is not link-edited with any other Language Environment modules, Language Environment-wide installation run-time option defaults, established by CEEDOPT or CEEOPT, can be changed at any time on a region-by-region basis. While the use of CEEROPT itself is optional, and any run-time options in it are also optional, any run-time option that is specified must be designated as either overrideable (OVR) or nonoverrideable (NONOVR). In addition, a valid value must be specified for each suboption of each specified run-time option.

- The CEEXOPT macro also creates the CEEUOPT object module when CEEUOPT is assembled. CEEUOPT can be linked with an application program to establish user default options. Options in CEEUOPT’s invocation of CEEXOPT must not be designated as overrideable or nonoverrideable. However, their suboption values take precedence over those of any corresponding overrideable CEEDOPT option values.

For more information about CEEDOPT, CEEROPT and CEEUOPT, see "Specifying Run-Time Options" on page 117.

To invoke CEEXOPT to create the CEEUOPT module to specify user run-time option defaults, use the format of the IBM-supplied template CEEUOPT, as shown in Figure 49 on page 125. It is a sample of CEEUOPT with the default suboption values for each of the run-time options, which establish application defaults.

See "z/OS Language Environment Customization" for information on CEEDOPT, CEEROPT and CEEUOPT, which are used to establish installation or region defaults.

---

**Figure 49. Sample Invocation of CEEXOPT within CEEUOPT Source Program**
Notes on CEEXOPT Invocation

You should be aware of the following considerations when invoking CEEXOPT:

- A continuation character (X in the source) must be present in column 72 on each line of the CEEXOPT invocation except the last line. This applies to CEEUOPT, CEEDOPT and CEEROPT.

- Options and suboptions must be specified in uppercase. Only suboptions that are strings can be specified in mixed case or lowercase. For example, both MSGFILE=(SYSOUT) and MSGFILE=(sysout) are acceptable. ALL31=(off) is not acceptable.

- A comma must end each option except for the final option. If the comma is omitted, everything following the option is treated as a comment.

- If one of the string suboptions contains a special character, such as embedded blank or unmatched right or left parenthesis, the string must be enclosed in apostrophes (' '), not in quotation marks (" "). (A null string can be specified with either adjacent apostrophes or adjacent quotation marks.)

  To get a single apostrophe (') or a single ampersand (&) within a string, two instances of the character must be specified. The pair is counted as only one character in determining if the maximum allowable string length has been exceeded, and in setting the effective length of the string.

- Macro instruction operands cannot exceed 255 characters in length. Therefore, it is not possible for each suboption of the TEST|NOTEST option to attain the maximum allowable length normally permitted by Language Environment. For example, the command suboption of the TEST option permits 250 characters, while the preference_file suboption allows 80. The total number of characters for these two suboptions, therefore, exceeds that allowed by the CEEXOPT macro. See Language Environment Programming Reference for further information.

  If the number of characters to the right of the equal sign is greater than 255 for any keyword parameter in the CEEXOPT invocation in CEEUOPT, CEEDOPT or CEEROPT, a return code of 12 is produced for the assembly, and no options are parsed.

- Avoid unmatched apostrophes in any string. The error cannot be captured within CEEXOPT itself; instead, the assembler produces a message such as

  IEV063 *** ERROR *** NO ENDING APOSTROPHE

  which bears no particular relationship to the suboption in which the apostrophe was omitted. Furthermore, none of the options is properly parsed if this mistake is made.

- You can completely omit the specification of any run-time option in CEEROPT or CEEUOPT.
  - In CEEROPT, a valid value must be specified for each suboption of those run-time options which are included.
  - In CEEUOPT you can completely omit the specification of any suboption of those run-time options which are included. Default values are then supplied for each of the missing suboptions in the options control block that is generated, and these values are ignored at the time Language Environment merges the options.

  There are two recommended ways of omitting a suboption in CEEUOPT. The HEAP run-time option is used below to demonstrate:

  - Specify the option with only a comma following the equal sign:

    
    HEAP=,

    X
or

- Specify the option with empty parentheses and comma following the equal sign:
  
  \[
  \begin{align*}
  \text{HEAP} &= () , \\
  \text{X}
  \end{align*}
  \]

  In either case, the continuation character (X in this example) must still be present in column 72.

- In CEEUOPT you can use commas to indicate the omission of one or more suboptions for options having more than one suboption. For example, if you wish to specify only the second suboption of the STORAGE option, the omission of the 1st, 3rd, and 4th suboptions can be indicated in any of the following ways:

  \[
  \begin{align*}
  \text{STORAGE} &= (, \text{NONE}) , \\
  \text{STORAGE} &= (, \text{NONE}, ) , \\
  \text{STORAGE} &= (, \text{NONE,,}) , \\
  \text{X}
  \end{align*}
  \]

  Because suboptions are positional parameters, do not omit the comma if the corresponding suboption is omitted and another suboption follows.

- Options that permit only one suboption do not need to enclose that suboption in parentheses. For example, the COUNTRY option can be specified in CEEUOPT and CEEROPT in either of the following ways:

  \[
  \begin{align*}
  \text{COUNTRY} &= (\text{US}) , \\
  \text{COUNTRY} &= \text{US} , \\
  \text{X}
  \end{align*}
  \]

**Performance Considerations**

For optimal performance when using CEEUOPT and CEEROPT, code only those options that you want to change. This enhances performance by minimizing the number of options lines Language Environment must scan. Options and suboptions that are to remain the same as the installation defaults do not need to be repeated.

For example, if the only change you want to make is to define STACK with an initial value of 64K and an increment of 64K, include only that run-time option in CEEUOPT or CEEROPT, as shown in the following examples:

**CEEUOPT CSECT**

```plaintext
CEEUOPT AMODE ANY
CEEUOPT RMODE ANY

CEEEOPT STACK=(128K,128K)

END
```

**CEEROPT CSECT**

```plaintext
CEEROPT AMODE ANY
CEEROPT RMODE ANY

CEEEOPT STACK=((128K,128K,ANYWHERE,KEEP,512K,128K),OVR)

END
```
Using Run-Time Options
Part 2. Preparing an Application to Run with Language Environment

Running an application is generally the same under Language Environment as in earlier versions of a language’s run time. However, to take advantage of some of the features that a common execution environment offers, you must consider a number of different things when preparing an application to run in Language Environment.

When running applications in Language Environment, you must consider the target operating system. Under batch, TSO/E, CICS and IMS, the way that parameters are passed differs. To ensure consistency, Language Environment standardizes the parameters as much as possible. It is therefore important for you to know what Language Environment does to the format to ensure this consistency. Parameter list format information is detailed in Chapter 10, “Using Language Environment: Parameter List Formats,” on page 131 and Appendix D, “Operating System and Subsystem Parameter List Formats,” on page 593.

In addition to describing parameter list formats, this part describes how to manage return codes, and offers suggestions on how to make your Language Environment-conforming applications reentrant.
Chapter 10. Using Language Environment Parameter List Formats

This chapter describes how to pass parameters to external routines under Language Environment. The methods described do not apply to internal routines or to compiled code that invokes its own library routines. Each Language Environment-conforming HLL might have its own method for transferring control and passing arguments between internal routines.

Understanding the Basics

When writing a Language Environment-conforming application, it is important to consider how parameters are passed to the application on invocation. The type of parameter list created by the operating system and passed to Language Environment when an application is run varies according to the operating system or subsystem used. Language Environment repackages the various formats so that what is actually passed to the main routine when it is invoked on most supported operating systems is a halfword prefixed character string. In C and C++, you can pass arguments to the main routine through argv and argc. If you set up your C, C++, COBOL, or PL/I main routine according to the rules of the language, you generally do not need to do anything special to receive parameters from the operating system.

Fortran does not support passing parameters to a main routine.

On operating subsystems such as CICS and IMS, however, the parameter format that is passed might be different from what your main routine expects. In these cases, you must explicitly code your main routine to accept the format of the parameters as they are passed by CICS and IMS.

"Preparing Your Main Routine to Receive Parameters" on page 134 contains examples of how to code your main routine to receive parameters under any supported operating system or subsystem.

Additionally, some HLLs, such as C, C++, and PL/I, provide options that enable you to specify the format of the parameter list you expect to be passed to your main routine. For example, C programmers can specify the PLIST run-time option, which determines the parameter list format. If your HLL provides such an option, refer to one of the following for information on which settings you should select to run an application:

<table>
<thead>
<tr>
<th>Environment</th>
<th>Table</th>
</tr>
</thead>
<tbody>
<tr>
<td>TSO/E</td>
<td>19 on page 134</td>
</tr>
<tr>
<td>IMS</td>
<td>20 on page 136</td>
</tr>
<tr>
<td>CICS</td>
<td>21 on page 137</td>
</tr>
<tr>
<td>MVS</td>
<td>22 on page 137</td>
</tr>
</tbody>
</table>

When running most main routines, you do not need to explicitly access the parameter list. Language Environment provides the CEE3PRM callable service to query and return to your calling routine the parameter string passed to your main routine when it was invoked. The returned parameter string contains only program arguments. If no program arguments were specified, a blank string is returned. See z/OS Language Environment Programming Reference for more information about CEE3PRM.
In addition, some HLLs, such as C and C++, provide ways of identifying passed parameters to your main routine using constructs within the HLL itself. For more information, see "C and C++ Parameter Passing Considerations" on page 593.

**Argument Lists and Parameter Lists**

The terminology used to describe passing parameters to and from routines currently differs among Language Environment-conforming HLLs. Figure 50 summarizes the terminology used with Language Environment. In Figure 50, a calling routine passes an argument list to a called routine. That same list is referred to as a parameter list when it is received by the called routine. Under Language Environment, the formats of the argument and parameter lists are identical. The only difference between the two terms is whether they are being used from the point of view of the calling or the called routine.

![Figure 50. Call Terminology Refresher](image)

**Passing Arguments between Routines**

Language Environment-conforming HLLs use the semantic terms *by value* and *by reference* to indicate how changes in the argument values for a called routine affect the calling routine:

**By value**

Any changes made to the argument value by the called routine will not alter the original argument passed by the calling routine.

**By reference**

Changes made by the called routine to the argument value can alter the original argument value passed by the calling routine.

Under Language Environment you can pass arguments directly and indirectly as follows:

**Direct**  The value of the argument is passed directly in the parameter list. You cannot pass an argument by reference (direct).

**Indirect**  A pointer to the argument value is passed in the parameter list.

Table 17 on page 133 summarizes the semantic terms by value and by reference and the direct and indirect methods for passing arguments. The table shows what is passed to routines.
### Table 17. Semantic Terms and Methods for Passing Arguments in Language Environment

<table>
<thead>
<tr>
<th></th>
<th>By Value</th>
<th>By Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Direct</td>
<td>The value of the object is passed</td>
<td>Not allowed under Language Environment</td>
</tr>
<tr>
<td>Indirect</td>
<td>A pointer points to the value of an object</td>
<td>A pointer points to the object</td>
</tr>
</tbody>
</table>

Figure 51 illustrates these argument passing styles. In Figure 51, register 1 (R1) points to the value of an object, or to an argument list containing either a pointer to the value of an object or a pointer to the object.

Table 18. Default Passing Style per HLL (continued)

<table>
<thead>
<tr>
<th>Language</th>
<th>Default Argument</th>
</tr>
</thead>
</table>

Notes:
1. C++ also supports by reference (indirect), if a prototype specifies it (with ampersand (&)).
2. Other parameter passing styles supported are:
   • By value (Indirect) (COBOL BY CONTENT) by Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL370, and VS COBOL II
   • By value (Direct) (COBOL BY VALUE) by Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, and COBOL for MVS & VM
3. However, when SYSTEM(CICS) or SYSTEM(IMS) is specified, VisualAge PL/I and PL/I for MVS & VM main procedures assume by value (direct) for parameters (OS PL/I main procedures continue to assume by reference (indirect)). (See [*PL/I Argument Passing Considerations* on page 138 for a discussion of OPTIONS(BYVALUE).)
   PL/I and Fortran also support by value (indirect) (also known as *by content*), which you can obtain by passing an argument in parentheses, for example, A in CALL X((A), B).
4. XPLINK-compiled functions pass arguments by value by default. However it will pass as many arguments in registers as possible in order to reduce the call linkage overhead. See [*z/OS Language Environment Vendor Interfaces* for additional information.]

Preparing Your Main Routine to Receive Parameters

When coding a main routine to receive a parameter list from the operating system, consider the following items:

• The HLL in which your main routine is written
  HLL semantics determine how you code your main routine in order to receive a parameter list.
• The method of main routine invocation
  You should consider the environment (MVS, TSO, IMS, CICS) in which your main routine is invoked, as well as the commands used to invoke it.
• The compiler or run-time options that you must specify
  The settings of the C PLIST run-time option, the C++ PLIST compiler option, or the PL/I SYSTEM compiler option that you must specify are based on:
  – The operating system or subsystem where you invoke your main routine
  – The commands you use to invoke your main routine

The following tables summarize options to consider when preparing a main routine to receive parameters in each system or subsystem; the tables also provide sample coding for each HLL:

| C or C++ | In C, PLIST(HOST) is the default; PLIST(TSO) is supported for compatibility and acts the same as PLIST(HOST). argc and argv are set from the command buffer. In C++, this is the behavior by default. If you wish to see the TSO CPPL, specify PLIST(OS) and access the CPPL through __osplist. In C++, you must specify the PLIST(OS) compiler option. | For PLIST(HOST) behavior, see above. The following shows a sample that accesses the TSO CPPL:  
```c
#include <stdlib.h>  
typedef struct CPPL_STRUCT {  
    void * CPPLCBUF;  
    void * CPPLUPT;  
    void * CPPLPSCB;  
    void * CPPLECT;  
} CPPL;  
main()  
{  
    CPPL *cppl_ptr;  
    cppl_ptr = __osplist;  
    ...  
}
```

|           |                             | OPTIONS (MAIN NOEXECOPS); |
|           |                             | DCL PARM1...             |
|           |                             | DCL PARM2...             |
PL/I Argument Passing Considerations

The PL/I OPTIONS option of both the PROCEDURE statement and ENTRY declaration permits you to specify the mutually exclusive options BYVALUE and BYADDR.

**OPTIONS(BYVALUE)**

Specifies that the PL/I procedure expects arguments to be passed to it by value (direct). OPTIONS(BYVALUE) can be specified for external PROCEDURE statements and ENTRY declarations. It applies to all arguments and argument descriptors.

**OPTIONS(BYADDR)**

Specifies that the PL/I procedure expects arguments to be passed to it by reference (indirect) or by value (indirect). OPTIONS(BYADDR) can be specified for external PROCEDURE statements and for ENTRY declarations. It applies to all arguments and argument descriptors.

OPTIONS(BYVALUE) cannot be specified for the following constructs:

- **ENTRY statements:**
  ```
  ENTRY(N) OPTIONS(BYVALUE);
  /* invalid */
  ```

- **Declaration of a parameter:**
  ```
  PROC(ARG1);
  DCL ARG1 FIXED BIN(31) BYVALUE;
  /* invalid */
  ```

- **Parameter descriptor in an ENTRY declaration:**
  ```
  DCL T ENTRY(FIXED BIN(31) BYVALUE) EXTERNAL;
  /* invalid */
  ```

All parameters, parameter descriptors, or return values must be specified with either the POINTER or FIXED BIN(31) data type. Return values are passed back in register 15.

OPTIONS(BYADDR) is the default unless the external procedure specifies OPTIONS(MAIN) and is compiled with the SYSTEM(CICS) or SYSTEM(IMS) compiler option. In this case, OPTIONS(BYVALUE) is the default. In general, you should specify OPTIONS(BYVALUE) only for a main procedure with a SYSTEM option of IMS or CICS. If you specify OPTIONS(BYVALUE) for a main procedure with other system options, the parameter list is passed to the main procedure as is.

OPTIONS(BYVALUE) for a main procedure implies OPTIONS(NOEXECOPS).

PL/I does not support calls to routines that modify the body of an indirect argument list built by PL/I compiled code.
Chapter 11. Making Your Application Reentrant

This chapter shows you how to make your application reentrant. Reentrancy allows more than one user to share a single copy of a load module. If your application is not reentrant, each application that calls your application must load a separate copy of your application.

Understanding the Basics

The following routines must be reentrant:
- Routines to be loaded into the LPA or ELPA
- Routines to be used with CICS
- Routines to be preloaded with IMS

Your routine should be reentrant if it is a large routine that is likely to have multiple concurrent users. Less storage is used if multiple users share the routine concurrently. Reentrancy also offers some performance enhancement because there is less paging to auxiliary storage.

If you want your routine to be reentrant, ensure that it does not alter any static storage that is part of the executable program; if the static storage is altered, the routine is not reentrant and its results are unpredictable.

Making Your C/C++ Program Reentrant

Under C/C++, reentrant programs can be categorized by their reentrancy type as follows:

Natural reentrancy
The attribute of programs that contain no modifiable external data.
Natural reentrancy is not applicable to C++.

Constructed reentrancy
The attribute of applications that contain modifiable external data and require additional processing to become reentrant. By default, all C++ programs are made reentrant via constructed reentrancy.

Natural Reentrancy

A C program is naturally reentrant if it contains no modifiable external data. In C, the following are considered modifiable external data:
- Variables using the extern storage class
- Variables using the static storage class
- Writable strings

If your C program is naturally reentrant, you do not need to use the RENT compiler option. After compiling and binding, install it in one of the locations listed in "Installing a Reentrant Load Module" on page 141.

Constructed Reentrancy

A constructed reentrant program is created by using either of the following methods:
- Use the binder to combine all of the object modules produced by the C/C++ compiler when the target data set is a PDSE or HFS.
Reentrant Applications

- Use the prelinker to combine all of the object modules produced by the C/C++ compiler and pass the output to the binder when the target data set is a PDS. For more information about the prelinker see Appendix A, "Prelinking an Application," on page 569.

The compile-time initialization information from one or more object modules is combined into a single initialization unit.

Programs with constructed reentrancy are split into two parts:
- A variable or nonreentrant part that contains external data
- A constant or reentrant part that contains executable code and constant data

Each user running the program receives a private copy of the first part (mapped by either the binder or the prelinker), which is initialized at run time. The second part can be shared across multiple spaces or sessions only if it is installed in the link pack area (LPA) or extended link pack area (ELPA).

Generating a Reentrant Program Executable for C or C++

To generate a reentrant C object module, follow these steps:

1. For C, if your program contains external data, compile your source files using the RENT compiler option. For C++, compile your source files; by default the compiler builds reentrant programs using constructed reentrancy. See z/OS C/C++ User’s Guide for more information.

2. To produce an executable program:
   - If the target data set is a PDSE or HFS, use the binder to combine all of the input into an executable program
   - If the target data set is a PDS, use the prelinker to combine all of the input prior to passing it as input to the binder. You cannot run an object module through the prelinker more than once. Also, you must link-edit using the same platform you used for the prelink step.

3. To get the greatest benefit from reentrancy, install your executable program in one of the locations listed in “Installing a Reentrant Load Module” on page 141.

Making Your COBOL Program Reentrant

If you intend to have multiple users execute a COBOL program concurrently, make it reentrant by using the RENT compiler option. For information about specifying the RENT compiler option, see Enterprise COBOL for z/OS Programming Guide or COBOL for OS/390 & VM Programming Guide.

Making Your Fortran Program Reentrant

If you intend to have multiple users execute a Fortran program concurrently, make it reentrant by using the RENT compiler option. The object module produced by the compiler must then be separated into its nonshareable and shareable parts using the reentrancy separation tool.

The Fortran reentrancy separation tool is delivered under Language Environment, and with the exception of its name and the names of the cataloged procedures used to invoke it, its use and operation are the same as with the reentrancy separation tool provided by VS FORTRAN Version 2.
Table 23. Fortran Reentrancy Separation Tool and Language Environment Cataloged Procedures

<table>
<thead>
<tr>
<th>Fortran Member Name</th>
<th>Language Environment Member Name</th>
<th>Content</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFBVSFST</td>
<td>AFHXFSTA</td>
<td>Fortran reentrancy separation tool</td>
</tr>
<tr>

<td>Cataloged procedure to separate the nonshareable and shareable parts of an object module, and link-edit</td>
</tr>
<tr>
<td>VFT2RLG</td>
<td>AFHWRLG</td>
<td>Cataloged procedure to separate the nonshareable and shareable parts of an object module, link-edit, and execute</td>
</tr>
</tbody>
</table>

The Fortran reentrancy separation tool is a member of the CEE.SCEERUN data set. The Fortran reentrancy separation tool cataloged procedures are members of the CEE.SCEEPROC data set.

It is important to note that Fortran products from VS FORTRAN Version 1 Release 4 on produce reentrant object code; however, mixing Fortran object code with another HLL’s object code can cause the other HLL’s load module to become nonreentrant. This is due to the mechanism that Fortran uses to produce reentrant code.

For more information about creating reentrant Fortran programs, see VS FORTRAN Version 2 Programming Guide for CMS and MVS.

Making Your PL/I Program Reentrant

If you intend to have multiple users execute a PL/I program at the same time, make it reentrant by specifying the REENTRANT procedure option when you compile. For information about specifying the REENTRANT procedure option, see PL/I for MVS & VM Language Reference.

Installing a Reentrant Load Module

You will get the most benefit from reentrancy if you link the program with the RENT attribute and any other attributes you would normally use, and have your system programmer install the load module in the link pack area (LPA) or the extended link pack area (ELPA) of the system.

Installing a module in the LPA, ELPA or saved segment requires an initial program load (IPL) of your operating system. Modules may be added/removed from the dynamic LPA after an IPL using the SET PR0G=MVS console command.

Chapter 11. Making Your Application Reentrant 141
This section provides more information about Language Environment and the services it provides.
Chapter 12. Initialization and termination under Language Environment

This chapter describes initialization and termination under Language Environment. It describes how you can customize your applications during initialization and termination by using Language Environment run-time options, callable services, and user exits. It includes instructions on how to use return and abend codes to respond to initialization and termination actions, as well as to conditions that remain unhandled.

Understanding the basics

Initialization and termination establish the state of various parts of the Language Environment program management model that supports multilanguage applications. The program management model describes three major entities of a program structure:

- **Process**: A collection of resources (code and data).
- **Enclave**: A collection of program units consisting of at least one main routine.
- **Thread**: The basic unit of execution.

The z/OS UNIX System Services (z/OS UNIX) program management model differs somewhat from the Language Environment program management model. Refer to "Mapping the POSIX Program Management Model to the Language Environment Program Management Model" on page 164 for more information. For more detailed definitions of program management and other Language Environment terms, see Chapter 13, “Program Management Model,” on page 159.

When you run a routine, Language Environment initializes the run-time environment by creating a process, an enclave, and an initial thread. You can modify initialization by running a user exit, written either in assembler or in an HLL.

During termination, threads (either single or multiple, depending on whether your application is POSIX-conforming), enclaves, and processes are terminated. Through Language Environment’s run-time options and callable services for termination, you can control how a thread, enclave, or process terminates. For example, you can control whether an abend or a return code is generated from an application that terminates with an unhandled condition of severity 2 or greater. See "Termination behavior for unhandled conditions" on page 154.
Related Options and Services

Run-Time Options

ABTERMENC  Specifies whether an enclave terminates with an abend or with a return code and a reason code when there is an unhandled condition of severity 2 or greater

TERMTHDACT  Specifies the level of information that you want to receive after an unhandled condition of severity 2 or greater causes a thread to terminate

Callable Services

CEE3ABD  Terminates an enclave with or without clean-up
CEE3GRC  Returns the user enclave return code to your routine. Along with CEE3SRC, it allows you to use return code-based programming techniques.
CEE3PRM  Returns to your routine the parameter string specified when your application was invoked
CEE3SRC  Sets the user enclave return code, which is used to calculate the final enclave return code at termination

User Exits

CEEBXITA  An assembler user exit for enclave initialization, and enclave and process termination
CEEBINT  An HLL user exit (written in C, C++ (with C linkage), VisualAge PL/I or PL/I for MVS & VM, or Language Environment-conforming assembler) called at enclave initialization

See [Chapter 28, “Using Run-Time User Exits,” on page 457](#) for more information on user exits.

Preinitialization Interface

CEEPIPI  CEEPIPI performs various initialization functions

See [Chapter 30, “Using preinitialization services,” on page 515](#) for more information on the preinitialization interface.

See [z/OS Language Environment Programming Reference](#) for syntax information on run-time options and callable services.

Language Environment Initialization

During initialization, a process, an enclave, and then an initial thread are created. You can affect initialization at the enclave level, by using either the assembler or HLL user exits.

Process initialization sets up the framework to manage enclaves and initializes resources that can be shared among enclaves. Enclave initialization creates the framework to manage enclave-related resources and the threads that run within the enclave. Thread initialization acquires a stack and enables the condition manager for the thread.
What Happens During Initialization

When you run an application under Language Environment, the following sequence of events occurs:

1. Language Environment runs the assembler user exit CEEBXITA.
   CEEBXITA runs prior to initialization of the enclave.
   You cannot code the CEEBXITA Assembler User Exit as an XPLINK application. However, since CEEBXITA is called directly by Language Environment and not by the application, a non-XPLINK CEEBXITA can be statically bound in the same program object with an XPLINK application.
   You can modify the environment in which your application runs by:
   - Specifying certain run-time options
   - Allocating data sets and files
   - Listing abend codes to be passed to the operating system
   - Checking the values of program arguments
   IBM provides a default version of CEEBXITA and several samples you can use to customize your application to perform tasks such as enforcing a set of run-time options for a particular environment. Because CEEBXITA runs before any HLLs have been established, it is written in assembler language so that it can establish parameters such as stack size and trap settings for the HLLs.
   CEEBXITA can function as application-specific or installation-wide. If you customize CEEBXITA to do application-specific processing (for example, dynamically allocating files needed by your application), you must link the exit with the application load module. (Conversely, installation-wide user exits must be linked with the Language Environment initialization library routines.)
   An application-specific user exit has priority over an installation-wide exit, so you can customize a user exit for a particular application without affecting the installation default version.
   For more information on the function and location of the CEEBXITA user exit, see Chapter 28, “Using Run-Time User Exits,” on page 457.

2. Language Environment examines the load module and initializes all languages identified in the application.
   Under Language Environment, an interlanguage communication (ILC) application works as shown in Figure 52. Language Environment will also examine the load module and initialize an XPLINK environment (forcing the XPLINK(ON) run-time option) if the initial program was compiled with the XPLINK option. Because all the language conventions are already established and do not need to be initialized and terminated between calls to other routines, the processing is significantly faster when using Language Environment-conforming HLLs.

Language Environment--The Common Run-Time Environment

Figure 52. Language Environment ILC — Only One Run-Time Environment to Initialize

Performance Consideration: Language Environment initializes all languages included in an application, regardless of whether
Initialization and Termination

all of them are used. To optimize performance, include only those languages your application actually uses.

3. Language Environment runs the HLL user exit CEEBINT. CEEBINT lets you perform tasks such as recording accounting statistics or calling other user exits. You cannot code CEEBINT as an XPLINK application. However, since CEEBINT is called directly by Language Environment and not the application, a non-XPLINK CEEBINT can be statically bound in the same program object with an XPLINK application. You can write a customized version of CEEBINT in any Language Environment-conforming language except COBOL. COBOL applications can, however, use CEEBINT written in another language.

IBM provides an object module default version of CEEBINT that consists simply of an immediate return to the application. This default version is automatically link-edited with your application unless you provide a customized version of CEEBINT.

For more information on the function and location of the CEEBINT user exit, see Chapter 28, “Using Run-Time User Exits,” on page 457.

Language Environment Termination

Language Environment termination provides services that restore the operating environment to its original state after your application either runs to completion or terminates abnormally. You can affect termination through the use of run-time options, callable services, and user exits. For example, if an unhandled condition of severity code 2 or greater occurs, you can decide if Language Environment should issue a return code or an abend code to the application. See “Termination behavior for unhandled conditions” on page 154 for more information.

What causes termination

Under Language Environment, an application terminates when any of the following conditions occur:

- The last thread in the enclave terminates (which in turn terminates the enclave).
- The main routine in the enclave returns to its caller; that is, an implicit STOP is performed.
- An HLL construct issues a request for the termination of an enclave, for example:
  - C’s abort() function
  - C’s raise(SIGTERM) function
  - C’s _exit() function
  - COBOL’s STOP RUN statement
  - COBOL’s GOBACK statement in a main program
  - Fortran’s STOP statement
  - Fortran’s CALL SYSRCX, CALL EXIT, CALL DUMP, or CALL CDUMP statement
  - PL/I’s STOP or EXIT function
- A default POSIX signal is received, where the default is termination.
- An abend is requested by the application (that is, the application calls CEE3ABD).
- An unhandled condition of severity 2 or greater occurs. (See “Termination behavior for unhandled conditions” on page 154 for information.)
What happens during termination

The following sequence of events occurs during termination:

1. **C atexit()** functions are invoked, if present. They are not invoked if _exit calls for termination or if abnormal termination occurs. The behavior of pthread functions are undefined if the pthread functions are called from an atexit routine.

2. PL/I FINISH ON-units are invoked if established.

3. For normal termination, the enclave return code is set (see "Managing return codes in Language Environment" on page 151). For abnormal termination caused by an unhandled condition of severity 2 or greater, either a return code and reason code or an abend is returned, based on settings specified in CEEBXITA (see "Termination behavior for unhandled conditions" on page 154).

4. CEEBXITA is invoked for enclave termination after all application code has completed, but before any enclave resources are relinquished.

   You can modify CEEBXITA to request an abend and a dump. You cannot code the CEEBXITA Assembler User Exit as an XPLINK application. Because the environment is still active, the dump accurately reflects the state of the environment before an enclave is terminated.

5. The environment is terminated:
   - All enclaves are terminated
   - All enclave resources are returned to the operating system
   - Any files that Language Environment manages are closed
   - Debug Tool is terminated, if active

6. CEEBXITA is invoked for process termination after the environment is terminated. You can modify CEEBXITA to close files, request an abend, or request a dump. A dump requested at this point, however, does not have the degree of detail that one requested during enclave termination has.

   CEEBXITA is not invoked for process termination if there is an unhandled condition of severity 2 or greater, or if CEEBXITA requests an abend during enclave termination. For more information on the CEEBXITA assembler user exit, see Chapter 28, "Using Run-Time User Exits," on page 457.

Depending on the setting of the TERMTHDACT run-time option, you might receive a message, a trace of the active routines, or a dump when a condition of severity 2 or greater occurs. See z/OS Language Environment Programming Reference for more information on TERMTHDACT.

Thread termination

A thread terminating in a non-POSIX environment is analogous to an enclave terminating because Language Environment supports only single threads. See "Enclave termination" on page 150 for information on enclave termination.

**POSIX thread termination:** A thread terminates due to pthread_exit(), pthread_kill(), or pthread_cancel(), or simply returns from the start routine of the thread in a POSIX environment. When a thread issues a exit() or _exit() or encounters an unhandled condition, that thread terminates and all other active threads are also forced to terminate. The z/OS UNIX (POSIX) environment supports multiple threads; each thread is terminated, as follows:

- The stack storage associated with the thread is freed
- Language Environment user-written condition handlers are run, if present
- The thread status is set
- Cleanup handlers and destructor routines are driven
- The stack is collapsed
- HLL members are called for thread termination
Initialization and Termination

For more detailed information on POSIX functions, refer to the following resources:

- “Language Environment and POSIX Signal Handling Interactions” on page 233
- “Mapping the POSIX Program Management Model to the Language Environment Program Management Model” on page 164
- z/OS UNIX System Services User’s Guide

Enclave termination

When an enclave terminates, Language Environment releases resources allocated on behalf of the enclave and performs various other activities including the following:

- Calls HLL-specific termination routines for HLLs that were active during the executing of the program
- Runs Language Environment user-written condition handlers, if present
- Deletes modules loaded by Language Environment
- Frees all storage obtained by Language Environment services
- Calls the CEEBXITA assembler user exit for enclave termination
- Frees Language Environment control blocks for the enclave
- Depending on the setting in the HLL or assembler user exit, Language Environment sets a return code and reason code or an abend.
- Restores the program mask and registers to preinitialization values
- Returns control to the enclave creator

Process termination

Process termination occurs when the last enclave in the process terminates. Process termination deletes the structure that kept track of the enclaves within the process, releases the process control block (PCB) and associated resources, and returns control to the creator of the process.

Because Language Environment generally supports a single enclave running within a single process, termination of the enclave means that your application has terminated. For exceptions to the single enclave within a single process and an enclave return and reason code being returned to the invoker, see Chapter 31, "Using nested enclaves," on page 555. For POSIX process considerations, see below.

Language Environment explicitly relinquishes all resources it gets. Routines that get resources directly from the host system (such as opening a DCB) must explicitly relinquish the resource. If these resources are not explicitly released, the environment can be corrupted because Language Environment has no method for releasing these resources.

POSIX process termination:  In a z/OS UNIX environment, POSIX process termination maps to Language Environment enclave termination. For specific information on POSIX default signal action at POSIX process termination when running in a z/OS UNIX environment, see “Language Environment and POSIX Signal Handling Interactions” on page 233.

In a z/OS UNIX environment, the following occurs if the process being terminated is a child process:

- The parent process is notified with a wait or a waitpid or saving of the exit status code.
- A new parent process ID is assigned to all child processes of the terminated process.
Managing return codes in Language Environment

This section discusses how Language Environment calculates and uses return codes and reason codes during enclave termination. (The return codes between subroutine calls that are implemented with programming language constructs are addressed in the appropriate language-specific programming guides.)

Before Language Environment, some HLLs (in particular, C) handled conditions that occur in the run-time environment by using a return code-based model. Such a model typically allows return codes to be passed between called subroutines and from the main routine back to the operating system to communicate the status of requested operations. Language Environment, on the other hand, uses a condition-based model to communicate conditions, as described in Chapter 18, “Using Condition Tokens,” on page 285.

Although Language Environment supports applications that rely on passing return codes from called subroutines and checking these return codes, you are encouraged to use Language Environment condition handling mechanisms, such as user-written condition handlers, instead.

How the Language Environment enclave return code is calculated

When an enclave terminates, Language Environment provides a Language Environment enclave return code and an enclave reason code (sometimes called a return code modifier). The Language Environment enclave return code is calculated by summing the user return code generated by the HLL (see “Setting and altering user return codes” on page 152) and the enclave reason code (see “How the enclave reason code is calculated” on page 154) as follows:

Language Environment enclave return code = user return code + enclave reason code

The Language Environment enclave return code is placed in register 15, and the enclave reason code is placed in register 0.

C considerations

The Language Environment enclave return codes are incompatible with the return codes returned under the pre-Language Environment-conforming version of C.

Fortran considerations

Unlike the behavior of VS FORTRAN Version 2, where any abnormal termination is indicated with message AFB240 followed by an abend with user completion code 240, Language Environment treats an abend as a condition. The condition that represents an abend is the severity 3 condition with the message number 3250, which contains the system or user completion code and the reason code.

If this condition is not handled and the ABTERMENC(RETCODE) run-time option is in effect, then the enclave terminates with a return code of 3000 under MVS. When the ABTERMENC(ABEND) run-time option is in effect and Language Environment terminates the enclave because of an unhandled condition, an abend occurs.
Initialization and Termination

PL/I considerations
The severities of some PL/I conditions have been redefined from what they were in pre-Language Environment versions of PL/I. See z/OS Language Environment Run-Time Messages for details.

Setting and altering user return codes
User return codes can be set and altered by the CEE3SRC callable service and by language constructs. As described in the following sections, the user return code value is based on the reason an enclave terminates and the language of the routine that initiates termination.

For C and C++
If a normal return from main() terminates the application, the user return code value is 0. When a C or C++ routine terminates an enclave with a language construct such as exit(n) or return(n), the value of n is used. In either case, any user return codes set through CEE3SRC are ignored; likewise, in an ILC application, any user return codes set with PL/I language constructs are also ignored.

If the enclave terminates due to an unhandled condition of severity 2 or greater, the user return code value used is the last one set by either CEE3SRC or, in an ILC application, PL/I language constructs. If neither CEE3SRC nor PL/I language constructs set the user return code, the user return code value is 0. See "Termination behavior for unhandled conditions" on page 154 for information on unhandled conditions. See z/OS C/C++ Programming Guide for more information about C or C++ language constructs.

For COBOL
When a COBOL program initiates enclave termination, such as with a STOP RUN statement or a GOBACK statement in a main program, the user return code value is taken from the RETURN-CODE special register; any user return codes set through CEE3SRC are ignored. Likewise, in an ILC application, any user return codes set with PL/I language constructs are also ignored. Thus, you can set and alter the user return code and pass it across program boundaries in register 15.

See Enterprise COBOL for z/OS Programming Guide or COBOL for OS/390 & VM Programming Guide for details on the RETURN-CODE special register and COBOL language constructs.

If the enclave terminates due to an unhandled condition with severity 2 or greater, the RETURN-CODE special register is not used in the enclave return code calculation. Instead, the user return code value used is the last one set by either CEE3SRC or, in an ILC application, PL/I language constructs. If neither CEE3SRC nor PL/I language constructs have been used to set the user return code, the user return code value is 0. See "Termination behavior for unhandled conditions" on page 154 for information on unhandled conditions.

For Fortran
You can set and alter the user return code using the SYSRCS or SYSRCX Fortran services. You can test the value of this field using SYSRCT. Depending on how the enclave is terminated, the value of the user return code could become the enclave return code.

If the enclave terminates as a result of a STOP statement or a CALL SYSRCX statement that explicitly specifies a value to be used as a return code, then that value becomes the enclave user return code. For example, either of the following Fortran statements terminates the enclave and sets the enclave return code to 101:

- STOP 101
Initialization and Termination

- CALL SYSRCS(101)

If the enclave terminates as a result of a language construct that depends on a previously established enclave user return code, then the previously established enclave user return code becomes the enclave return code. For example, the following sequence of Fortran statements sets the enclave return code to 201:

- CALL SYSRCS(201)
- CALL EXIT

The call to SYSRCS sets the enclave user return code to 201 and the call to EXIT causes the enclave user return code to be used as the enclave return code.

The return code modifier depends on the operating system and the severity of the condition, as shown in Table 24.

<table>
<thead>
<tr>
<th>Condition Severity</th>
<th>Return Code Modifier</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>2000</td>
</tr>
<tr>
<td>3</td>
<td>3000</td>
</tr>
<tr>
<td>4</td>
<td>4000</td>
</tr>
</tbody>
</table>

If the enclave terminates due to an unhandled condition and the ABTERMENC(RETCODE) run-time option is in effect, then the enclave return code is the sum of the enclave user return code and the return code modifier. For example, when CALL SYSRCS(201) is executed and termination occurs as a result of an unhandled condition of severity 3, the enclave return code is 3201.

For PL/I

You can set and alter the user return code with the PLIRETC function or the OPTIONS(RETCODE) attribute. The PLIRETV function retrieves the current value of the user return code.

When a PL/I routine initiates enclave termination, such as with a STOP or EXIT statement in a subroutine or with a RETURN or END statement in a main procedure, the user return code is the value set with the PLIRETC function or the OPTIONS(RETCODE) attribute. However, CEE3SRC can alter the user return code set with PLIRETC or the OPTIONS(RETCODE) attribute. If CEE3SRC was the last method used to set the user return code, the last three bytes of the return-code set by CEE3SRC are used as the user return code.

If the enclave terminates due to an unhandled condition with severity 2 or greater, the user return code value set last (with either PL/I constructs or CEE3SRC) is used in the calculation of the enclave return code; if one has not been set, the user return code value is 0. See “Termination behavior for unhandled conditions” on page 154 for information on unhandled conditions.

CEE3SRC and CEE3GRC are not supported in PL/I multitasking applications.

See VisualAge PL/I Language Reference or PL/I for MVS & VM Language Reference for details on PL/I language constructs.
Initialization and Termination

How the enclave reason code is calculated

The enclave reason code provides additional information in support of the enclave return code. Language Environment calculates the enclave reason code by multiplying a severity code (that indicates how an enclave terminated) by 1000.

The severity code is initially set to 0, indicating normal enclave termination. If the Termination_Imminent due to STOP (T_L_S) condition is signaled, it is set to 1. If the enclave terminates due to an unhandled condition of severity 2 or greater, the enclave reason code is set according to the severity of the unhandled condition that caused the enclave to terminate, as shown in Table 25. For more information about Language Environment conditions and severity codes, see Table 32 on page 202.

Table 25: Summary of Enclave Reason Codes

<table>
<thead>
<tr>
<th>Condition Severity</th>

</tr>
<tr>
<td>Unhandled severity 4 condition</td>
<td>Critical error — abnormal termination</td>
<td>4000</td>
</tr>
</tbody>
</table>

Termination behavior for unhandled conditions

When there is an unhandled condition of severity 2 or greater, you can choose whether an enclave terminates with an abend or with a return code and a reason code. Language Environment will assign an abend code and return and reason code, as described in this section, or you can assign values yourself, as described in “Setting and altering user return codes” on page 152.

See Table 32 on page 202 for a discussion of conditions and how they are handled in Language Environment, and “Language Environment and POSIX Signal Handling Interactions” on page 233 for specific information pertaining to POSIX signal action defaults and unhandled conditions in a z/OS UNIX environment.

Some users, especially those using COBOL or running IMS applications, expect to receive an abend when an error is detected rather than a return code and a reason code. To get this behavior, they can use the ABTERMENC(ABEND) run-time option discussed in “Abend codes generated by ABTERMENC(ABEND) run-time option” on page 155. Other users, however, expect to receive a return code and a reason code when there is an error.

If you are running in a CICS environment, the IBM-supplied default is to terminate the enclave with an abend for unhandled conditions of severity 2 or greater.

If you are running in a non-CICS environment and you expect the enclave to terminate with a return code and a reason code for unhandled conditions of severity 2 or greater, you can use the ABTERMENC(RETCODE) run-time option and the
CEEBXITA assembler user exit. The default version of CEEBXITA for non-CICS environments requests that the enclave terminate with a return code and a reason code.

Table 26 shows the various types of enclave termination that occur based on the ABTERMENC run-time option settings and the CEEAUE_ABND flag settings of CEEBXITA. See “CEEBXITA Assembler User Exit Interface” on page 463 for an explanation of the CEEAUE_ABND flag.

<table>
<thead>
<tr>
<th>ABTERMENC Suboption</th>

</tr>
</tbody>
</table>

Determining the abend code

You can choose the abend code you want Language Environment to use, based on whether the abend is requested by the assembler user exit or whether the ABTERMENC(ABEND) run-time option is used.

Abend codes generated by CEEBXITA

When you request an abend through CEEBXITA, the values contained in certain fields of the exit are used for the abend code and the reason code. Table 27 shows the abend codes used by Language Environment when CEEBXITA requests an abend and does not modify the CEEAUE_RETC code field.

<table>
<thead>
<tr>
<th>Condition Severity</th>
<th>User Return Code</th>

<td>Transaction abend 3000</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>User abend 4000</td>
<td>Transaction abend 4000</td>
</tr>
</tbody>
</table>

Abend codes generated by ABTERMENC(ABEND) run-time option

Language Environment terminates the enclave with the same abend code that caused the unhandled condition of severity 2 or greater if all of the following are true:

- You use the ABTERMENC(ABEND) run-time option.
- The unhandled condition was generated by an abend.
- The assembler user exit does not alter the CEEAUE_ABND flag setting.

Table 28 on page 156 shows the abend code and reason code used when the enclave terminates due to the various unhandled conditions of severity 2 or greater and ABTERMENC(ABEND) is specified in both CICS and non-CICS environments.
Table 28. Abend Code Values Used by Language Environment with ABTERMENC(ABEND)

<table>
<thead>
<tr>
<th>Unhandled Condition</th>
<th>Abend Code</th>
<th>Abend Reason Code</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABEND</td>
<td>The original abend code</td>
<td>In non-CICS environment, the original abend reason code</td>
</tr>
<tr>
<td>Program interrupt</td>
<td>See [Program interrupt abend and reason codes] for program interrupt abend codes</td>
<td></td>
</tr>
<tr>
<td>Software-raised condition</td>
<td>A user 4038 abend is used in a non-CICS environment and a transaction 4038 abend is used in a CICS environment</td>
<td>In a non-CICS environment, X'1'</td>
</tr>
<tr>
<td>Unsuccessful LOAD (non-CICS)</td>
<td>The abend code that would have been used by the operating system.</td>
<td>The abend reason code that would have been used by the operating system.</td>
</tr>
</tbody>
</table>

**Note:** In a CICS environment, when an abend is issued, only the abend code is returned. CICS does not return an abend reason code.

Program interrupt abend and reason codes

A program interrupt can cause an unhandled condition of severity 2 or greater. When running with the ABTERMENC(ABEND) run-time option in a CICS environment, an abend code of ASRA is issued for program interrupts. When running with the ABTERMENC(ABEND) run-time option in a non-CICS environment, the abend codes and reason codes shown in Table 29 are issued for program interrupts.

1. The operating system issues abend code S0C4 reason code 10 for segment translation program interrupts.
2. The operating system issues abend code S0C4 reason code 11 for page translation program interrupts.
Initialization and Termination
Chapter 13. Program Management Model

Now that you have been introduced to how applications run in Language Environment, you need to understand the model of program management under which Language Environment operates. Understanding the model helps you recognize equivalent entities across Language Environment-conforming programming languages and predict how your single- and mixed-language applications run. This chapter provides an overview of the Language Environment model.

The Language Environment program management model supports the language semantics of applications that run in the common run-time environment and defines the way routines or programs are put together to form an application. Language Environment implements a subset of the POSIX program management model. Features not supported in z/OS Language Environment are indicated in this manual.

The POSIX program management model differs somewhat from the Language Environment program management model. Refer to "Mapping the POSIX Program Management Model to the Language Environment Program Management Model" on page 164 for more information.

Understanding the Basics

The Language Environment program management model has three basic entities — the process, enclave, and thread, each of which Language Environment creates whenever you start execution of an HLL application. This section describes each of these entities and their relationship to program management.

Language Environment Program Management Model Terminology

Some terms used to describe the program management model are common programming terms; others have meanings that are specific to a given language. It is important that you understand the meaning of the terminology Language Environment uses and how it compares with existing languages. For more detailed definitions of these and other Language Environment terms, please consult the glossary in z/OS Language Environment Concepts Guide.

Language Environment Terms and Their HLL Equivalents

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Process</td>
<td>The highest level of the Language Environment program management model; a collection of resources, both program code and data, consisting of at least one enclave.</td>
</tr>
<tr>
<td>Enclave</td>
<td>The enclave defines the scope of HLL semantics. In Language Environment, a collection of routines, one of which is designated as the main routine. The enclave contains at least one thread. Equivalent HLL terms: C or C++ – program, consisting of a main C or C++ function and its subroutines, COBOL – run unit, Fortran – executable program, consisting of a main Fortran program and its subprograms, PL/I – main procedure and all its subprocedures.</td>
</tr>
<tr>
<td>Thread</td>
<td>An execution entity that consists of synchronous invocations and terminations of routines. The thread is the basic run-time path within.</td>
</tr>
</tbody>
</table>
Program Management Model

the Language Environment program management model;
dispatched by the system with its own run-time stack, instruction
counter, and registers.

**Routine**
In Language Environment, either a procedure, function, or
subroutine.

Equivalent HLL terms: C or C++ – function, COBOL – program,
Fortran – program, PL/I – procedure, BEGIN/END block.

**Terminology for Data**

**Automatic data**
Data that does not persist across calls. In the absence of a specific
initializer, automatic data get “accidental” values that may depend on the
behavior of the caller or the last function to be called by the caller.

**External data**
Data with one or more named points by which the data can be referenced
by other program units and data areas. External data is known throughout
an enclave.

**Local data**
Data known only to the routine in which it is declared; equivalent to local
data in C, C++, or Fortran, any non-EXTERNAL data items in COBOL, and
data with the PL/I INTERNAL attribute (whether implicitly, or by explicit
declaration).

[Figure 53 on page 161](#) shows the simplest form of the Language Environment
program management model and the resources that each component controls.
Refer to the figure as you read about the program management model.
Processes

A process is a collection of resources, both application code and data, consisting of one or more related enclaves (described in the next section). The process is the outermost or highest level run-time component of the common run-time environment. The resources maintained at the process level do not affect the language semantics of an application running at the enclave level.

The Language Environment library is an example of the type of resource that is maintained at the process level. The Language Environment library is loaded at process initialization, although it could be loaded for any of the individual enclaves within the process at enclave initialization. The process is used in the same way by all enclaves created within the process. It has no effect on the HLL semantics of applications running within each of the enclaves.

Each process has an address space that is logically separate from those of other processes. Except for communications with each other using certain Language Environment mechanisms, no resources are shared between processes; processes do not share storage, for example. A process can create other processes. However, all processes are independent of one another; they are not hierarchically related.
Program Management Model

Although the Language Environment program model supports applications consisting of one or more processes, z/OS Language Environment supports only a single process for each application that runs in the common run-time environment.

Enclaves

A key feature of the program management model is the enclave, which consists of one or more load modules, each containing one or more separately compiled, bound routines. A load module can include HLL routines, assembler routines, and Language Environment routines.

The Enclave Defines the Scope of Language Semantics

By definition, the scope of a language statement is that portion of code in which it has semantic effect. The enclave defines the scope of the language semantics for its component routines, just as a COBOL run unit defines the scope of semantics of a COBOL program. Scope encompasses names, external data sharing, and control statements such as C’s `exit()`, COBOL’s STOP RUN, Fortran’s STOP, and PL/I’s STOP and EXIT statements.

The Enclave Defines the Scope of the Definition of the Main Routine and Subroutines: The enclave boundary defines whether a routine is a main routine or a subroutine. The first routine to run in the enclave is known as the main routine in Language Environment. All others are designated subroutines of the main routine.

The first routine invoked in the enclave must be capable of being designated main according to the rules of the language of the routine. For example, a main routine in a Language Environment-conforming PL/I application would be the PROC OPTIONS (MAIN) routine. All other routines invoked in the enclave must be capable of being a subroutine according to the rules of the languages of the routines.

If a routine is capable of being invoked as either a main or subroutine, and recursive invocations are allowed according to the rules of the language, the routine can be invoked multiple times within the enclave. The first of these invocations could be as a main routine and the others as subroutines.

The Enclave Defines the Scope and Visibility of the Following Types of Data:

- Automatic data: Automatic data is allocated with the same value on entry and reentry into a routine if it has been initialized to that value in the semantics of the language used, for example, data declared using the PL/I INIT() option. Values of the data at exit from the routine are not retained for the next entry into the routine. The scope of automatic data is a routine invocation within an enclave.

- External data: External data persists over the lifetime of an enclave and retains last-used values whenever a routine is reentered. The scope of external data is that of the enclosing enclave; all routines invoked within the enclave recognize the external data. Examples are C or C++ data objects of extern storage class, COBOL data items defined with the EXTERNAL attribute, Fortran common blocks, and PL/I data declared as EXTERNAL.

- Local data: The scope of local data is that of the enclosing enclave; however, local data is recognized only by the routine that defines it. Examples are any C or PL/I variable with block scope, any Fortran data declared as AUTOMATIC, and any non-EXTERNAL data item in COBOL.

The Enclave Defines the Scope of Language Statements: The enclave defines the scope of language statements — for example, those that stop execution of the outermost routine within an enclave. C’s `exit()`, COBOL’s STOP RUN, Fortran’s...
STOP and END statements, and PL/I’s STOP and EXIT statements are examples of such statements. When one of these statements is executed, the main routine within the enclave terminates. Thus, the enclave defines the scope of the language statements.

Prior to returning, resources obtained by the routines in the enclave are released and any open files (other than the Language Environment message file) are closed.

Additional Enclave Characteristics

Management of Resources: The enclave manages most Language Environment resources, such as the thread and heap storage, other than the message file (which is managed as a process-level resource). Heap storage, for example, is shared among all threads within an enclave. Allocated heap storage remains allocated until explicitly freed or until the enclave terminates. None of the enclave-managed resources is shared between enclaves.

Multiple Enclaves: z/OS Language Environment provides explicit support for a single enclave within a single process. Under some circumstances, however, multiple enclaves can exist within a single process. A description of how to create multiple, or nested, enclaves can be found in Chapter 31, “Using nested enclaves,” on page 555.

Threads

Within each enclave is a thread, the basic run-time path represented by the machine state; conditions raised during execution are isolated to that run-time path.

Threads share all of the resources of an enclave and therefore do not need to selectively create or load new copies of resources, code, or data. Although a thread does not own its storage, it can address all storage within the enclave. All threads are independent of one another and are not related hierarchically. A thread is dispatched with its own run-time stack, instruction counter, registers, and condition handling mechanisms.

Because threads operate with unique run-time stacks, they can run concurrently within an enclave and allocate and free their own storage. Concurrent, or parallel, processing, is useful when code is event-driven, or for improving the performance of a large application.
Mapping the POSIX Program Management Model to the Language Environment Program Management Model

Language Environment in conjunction with z/OS UNIX supports POSIX standards (POSIX 1003.1 and POSIX 1003.1c) and the XPG4 standard. The POSIX standard follows a program management model which differs somewhat from the Language Environment program management model. This section provides a helpful comparison of both models.

The descriptions below are intended to be a brief review for C users of the characteristics of POSIX program entities. For full definitions of these terms, refer to the ISO/IEC9945 for POSIX 1003.1 and POSIX 1003.1c. The XPG4 standard is described in detail in X/Open Specification Issue 4.

Key POSIX Program Entities and Language Environment Counterparts

POSIX defines four program model constructs:

Process

An address space, at least one thread of control that executes within that address space, and the thread’s or threads’ required system resources.

In general, POSIX processes are peers; they run asynchronously and are independent of one another, unless your application logic requests otherwise.
Some aspects of selected processes are hierarchical, however. A C process can create another C process (no ILC is allowed) by calling the fork() or spawn() functions. Certain function semantics are defined in terms of the parent process (the invoker of the fork) and the child process (cloned after the fork). For example, when a parent process issues a wait() or waitpid(), the parent process’ logic is influenced by the status of the child process or processes.

A Language Environment process with a single enclave maps approximately to a POSIX process. In Language Environment, starting a main routine creates a new process. In POSIX, issuing a fork() or a spawn() creates a new process. A POSIX sigaction of stop, terminate, or continue applies to the entire POSIX process.

A Language Environment process with multiple enclaves is a Language Environment extension to POSIX. If a process contains more than one enclave, only the first enclave in the process can have POSIX(ON) specified. All of the nested enclaves must be POSIX(OFF). A process that contains any POSIX(OFF) enclaves cannot issue a fork() or a spawn(), either explicitly or implicitly (popen() being mapped to fork() and exec()).

**Note:** The scope of a specific POSIX function might be the Language Environment process or Language Environment enclave. See [Scope of POSIX Semantics](#) for details.

### Process group
Collection of processes. Group membership allows member processes to signal one another, and affects certain termination semantics.

No Language Environment entity maps directly to a POSIX process group.

### Session
Collection of process groups. Conceptually, a session corresponds to a logon session at a terminal.

No Language Environment entity maps directly to a POSIX session, but a session is a rough equivalent of a Language Environment application whose execution scope is bounded by the end user logon and logoff.

### Thread
A single flow of control within a process. Each thread has its own thread ID, state of any timers, errno value, thread-specific bindings, and the required system resources to support a flow of control. Threads are independent and not hierarchically related.

A Language Environment thread maps to a POSIX thread. POSIX pthread_create creates a new thread under Language Environment.

An enclave that contains multiple threads cannot issue fork(), either explicitly or implicitly (popen() being mapped to fork() and exec()).

**Scope of POSIX Semantics**

Some general rules for the scope of POSIX processes follow, as illustrated in Figure 55 on page 166:

- POSIX semantics applied to a POSIX process from outside the POSIX process (interprocess semantics) are applied to a Language Environment process. For example, a signal directed from a process to another process using kill is applied to a Language Environment process.
Program Management Model

- POSIX semantics scoped to within the current POSIX process (intraprocess semantics) apply to the current Language Environment enclave. For example, heap storage is recognized throughout an enclave.

Figure 55. Scope of Semantics against POSIX Processes and Language Environment Processes/Enclaves
Chapter 14. Stack and heap storage

Language Environment provides services that control the stack and heap storage used at run time. Language Environment-conforming HLLs and assembler routines use these services for all storage requests.

Understanding the basics

Language Environment provides the following types of storage:

- Stack storage

  *Stack storage* is automatically created by Language Environment and is used for routine linkage and automatic storage. Refer to “Stack storage overview” on page 169 for more information.

- Heap storage

  *Heap storage* is dynamically allocated at a routine's first request for storage that has a lifetime not related to the execution of the current routine. You can control allocation and freeing of heap storage using Language Environment callable services. Refer to “Heap storage overview” on page 171 for more information.

Table 30 summarizes the ways in which Language Environment-conforming languages use stack and heap storage. The remainder of this section further discusses stack and heap storage concepts and terminology.

Stack storage overview

**Note:** The term stack, as used in this chapter, refers to the user stack, which is an independent area of stack storage that can be located above or below the 16 MB line, designed to be used by both library routines and compiled code. All references to stack storage and stack frame in this chapter are to real storage allocation, as opposed to invocation stack, which refers to a conceptual stack.

Stack storage is the storage provided by Language Environment that is needed for routine linkage and any automatic storage. It is allocated on entry to a routine or block, and freed on the subsequent return. It is a contiguous area of storage obtained directly from the operating system. Stack storage is automatically provided at thread initialization and is available in the user stack.

The user stack is used by both library routines and, except for Fortran, compiled code. Stack storage is also available in the library stack, which is an independent area of stack storage, allocated below the 16 MB line, designed to be used only by library routines.

A storage stack is a data structure that supports procedure or block invocation (call and return). It is used to provide both the storage required for the application initialization and any automatic storage used by the called routine. Each thread has a separate and distinct stack.

The storage stack is divided into large segments of storage called stack segments, which are further divided into smaller segments called stack frames, also known as dynamic storage areas (DSAs). A stack frame, or DSA, is dynamically acquired storage composed of a register save area and an area available for dynamic storage allocation for items such as program variables. Stack frames are added to the user stack when a routine is entered, and removed upon exit in a last in, first out (LIFO) manner. Stack frame storage is acquired during the execution of a program and is allocated every time a procedure, function, or block is entered, as, for example, when a call is made to a Language Environment callable service, and is freed when the procedure or block returns control.

The first segment used for stack storage is called the initial stack segment. When the initial stack segment becomes full, a second segment, or stack increment is obtained from the operating system. As each succeeding stack increment becomes full, another is obtained from the operating system as needed. The size of the initial stack segment and the size of the increments are specified by the init_size and incr_size parameters of the STACK run-time option. If the STACK option is not specified, Language Environment uses the installation default or application default as the initial stack segment size (see z/OS Language Environment Programming Reference for more information on using the STACK run-time option).

Figure 56 on page 170 shows the standard Language Environment stack storage model. The XPLINK stack (see Figure 17 on page 32) is structured differently. See Chapter 3, “Using Extra Performance Linkage (XPLINK),” on page 29 for information about XPLINK.
**Tuning stack storage**

For best performance, the initial stack segment should be large enough to satisfy all requests for stack storage. The Language Environment storage report generated by the RPTSTG(ON) option (see z/OS Language Environment Programming Reference) shows you how much stack storage is being used, the total number of segments allocated to the stack, and the recommended values for the STACK run-time option. An initial stack segment that is too large can waste storage and degrade overall system performance, especially under CICS where storage is limited.

You can tune stack storage by using the Language Environment STACK and THREADSTACK run-time options; consult z/OS Language Environment Programming Reference for details.

RPTSTG(ON) and the STORAGE run-time option (see z/OS Language Environment Programming Reference) can have a negative affect on the performance of your application, because as the application runs, statistics are kept on storage requests. Therefore, always use the IBM-supplied default setting RPTSTG(OFF) when running production jobs. Use RPTSTG(ON) and STORAGE only when debugging or tuning applications.

**COBOL storage considerations**

Storage for data items declared in the COBOL LOCAL-STORAGE SECTION is allocated from the Language Environment user stack. The storage location of data items declared in COBOL LOCAL-STORAGE SECTION is controlled by the Language Environment STACK option. The COBOL compiler options do not affect the location of data items declared in the COBOL LOCAL-STORAGE SECTION.

**PL/I Storage considerations**

PL/I automatic storage is provided by the Language Environment user stack. Automatic storage above the 16 MB line is supported under control of the Language Environment STACK and THREADSTACK run-time options. When the Language Environment user stack is above 16 MB, PL/I temporaries (dummy arguments) and parameter lists (for reentrant/recursive blocks) also reside above 16 MB. As long as
Stack and Heap Storage

an OS PL/I application does not contain edited stream I/O (for example, the EDIT option is not used in a PUT statement) and is running with AMODE(31), you can relink it with Language Environment to allow for STACK(,,ANY) to be used. For VisualAge PL/I and PL/I for MVS & VM, as long as the application is AMODE(31), STACK(,,ANY) is supported. The stack frame size for an individual block is constrained to 16 MB, which means the size of an automatic aggregate, temporary variable, or dummy argument cannot exceed 16 MB.

Heap storage overview

Heap storage is used to allocate storage that has a lifetime not related to the execution of the current routine; it remains allocated until you explicitly free it or until the enclave terminates. You can control allocation and freeing of heap storage using Language Environment callable services, and tune heap storage using the Language Environment run-time options HEAP, THREADHEAP and HEAPPOOLS; see z/OS Language Environment Programming Reference for details.

Heap storage is shared among all program units and all threads in an enclave. Any thread can free heap storage. You can free one element at a time with the CEEFRST callable service, or you can free all heap elements at once using CEEDSHP. You cannot, however, discard the initial heap.

Storage can be allocated or freed with any of the HLL storage facilities, such as malloc(), calloc(), or ALLOCATE, along with the Language Environment storage services. For HLLs with no intrinsic function for storage management, such as COBOL, you can use the Language Environment storage services.

Note that when HEAPPOOLS(ON) is in effect, the C storage management intrinsic functions must be used together; that is, if you malloc(), you must use free() to release the storage, you cannot use CEEFRST. See Using HEAPPOOLS to improve performance on page 173 for more information about heap pools.

Heap storage, sometimes referred to as a heap, is a collection of one or more heap segments comprised of an initial heap segment, which is dynamically allocated at the first request for heap storage, and, as needed, one or more heap increments, allocated as additional storage is required. The initial heap is provided by Language Environment and does not require a call to the CEECRHP service. The initial heap is identified by heap_id=0. It is also known as the user heap. See Figure 57 on page 173 for an illustration of Language Environment heap storage.

Heap segments, which are contiguous areas of storage obtained directly from the operating system, are subdivided into individual heap elements. Heap elements are obtained by a call to the CEEGTST service, and are allocated within each segment of the initial heap by the Language Environment storage management routines. When the initial heap segment becomes full, Language Environment gets another segment, or increment, from the operating system.

The size of the initial heap segment is governed by the init_size parameter of the HEAP run-time option. (See z/OS Language Environment Programming Reference.) The incr_size parameter governs the size of each heap increment.

A named heap is set up specifically by a call to the CEECRHP service, which returns an identifier when the heap is created. Additional heaps can also be created and controlled by calls to CEECRHP.
Stack and Heap Storage

Additional heaps provide isolation between logical groups of data in different additional heaps. Separate additional heaps when you need to group storage objects together so they can be freed at once (with a single call to CEEDSHP), rather than freed one element at a time (with calls to CEEFRST).

Library routines occasionally use a heap called the library heap for storage below 16 MB. The size of this heap is controlled by the BELOWHEAP run-time option. The library heap and the BELOWHEAP run-time option have no relation to heaps created by CEECRHP. If an application program creates a heap using CEECRHP, library routines never use that heap (except, of course, the storage management library routines CEEGTST, CEEFRST, CEECZST, and CEEDSHP). The library heap can be tuned with the BELOWHEAP run-time option.

The Language Environment anywhere heap and below heap are reserved for run-time library usage only. Application data and variables are not kept in these heaps. You normally should not adjust the size of these heaps unless the storage report indicates excessive segments allocated for the anywhere or below heaps, or if too much storage has been allocated.

You can use the Language Environment STORAGE option to diagnose the use of uninitialized and freed storage.

Language Environment provides a memory leak analysis tool (MEMCHECK) to perform the following functions:

- Check for heap storage leaks, double frees, overlays and print them in a report.
- Trace user heap storage allocation and deallocation requests and print them in a report.

See [z/OS Language Environment Debugging Guide](https://www.ibm.com/support/docview.wss?uid=swg27053277) for more information on MEMCHECK.

You can use the HEAPCHK run-time option to run heap storage tests, and to help identify storage leaks.

[Figure 57 on page 173](https://www.ibm.com/support/docview.wss?uid=swg21417703) shows the Language Environment heap storage model.
Using HEAPPOOLS to improve performance

Heap pools is an optional storage allocation algorithm for C/C++ applications that is much faster than the normal malloc()/free() algorithm in most circumstances. The algorithm is designed to avoid contention for storage in a multithreaded application, and therefore it is important to investigate if your application can benefit from its use.

The heap pools algorithm allows for between one and twelve pools of storage cells out of the heap. The sizes of the cells and cell pool extents are specified by the HEAPPOOLS run-time option, which is also used to enable the heap pools algorithm.

**Note:** Use of the Vendor Heap Manager (VHM) overrides the use of the HEAPPOOLS run-time option.

Applications which should use heap pools

The following types of applications can benefit from the use of heap pools:

- Multi-threaded applications: although single-threaded applications can benefit from the heap pools algorithm, multi-threaded applications can get the most benefit because the proper use of heap pools virtually eliminates contention for heap storage.

- Applications which issue many storage requests with a malloc() of 2048 bytes or less, because the heap pools algorithm is not used in a malloc() that is greater than 2048 bytes.

- Applications that are not storage constrained: the heap pools algorithm gives up storage for speed. When untuned, the heap pools algorithm uses much more storage than the normal malloc()/free() algorithm; when properly tuned it uses only slightly more. Therefore, storage constrained applications should try heap pools, but only if the cell sizes and cell pool percentages are carefully tuned. (For tuning information, see “Tuning heap storage” on page 174.) It is possible that some applications running with the heap pools algorithm will have to increase their region size.
Heap IDs recognized by the Language Environment heap manager

Table 31 lists Language Environment heaps and their respective purposes.

AMODE considerations for heap storage

The initsz24 and incrsz24 parameters of the HEAP run-time option control the initial size and subsequent increments of heap storage allocated below the 16 MB line. This storage is required for AMODE(24) applications running with the ALL31(OFF) and HEAP(,,ANYWHERE) run-time options in effect.

For example, suppose the initial heap segment is allocated above 16 MB. If an AMODE(24) routine requests storage from this initial heap, Language Environment must allocate a heap segment from below the 16 MB line so that the AMODE(24) routine can address the storage.

When a Fortran program is in AMODE(24), heap storage is allocated below the 16 MB line. The allocation of heap storage in a Fortran common block is sensitive to the AMODE setting of the requester program. For example, if a requester in AMODE(31) calls a Fortran program in AMODE(24), heap storage is allocated above the 16 MB line as defined by the AMODE(31) setting of the requester.

OS PL/I uses HEAP(,,ANYWHERE) as the default location for heap storage. The allocation of heap storage is sensitive to the AMODE setting of the requester and the main program. If the requester is in AMODE(31) or HEAP(,,ANYWHERE) is in effect and the main program is in AMODE(31), heap storage is allocated above the 16 MB line.

There are some restrictions when using CEEGTST, the Get Heap Storage AWI, in an AMODE(24) COBOL program. See the description of CEEGTST in [z/OS Language Environment Programming Reference] for details on these restrictions.

Tuning heap storage

For best performance, the initial heap segment should be large enough to satisfy all requests for heap storage. The Language Environment storage report generated by the RPTSTG(ON) run-time option (see [z/OS Language Environment Programming Reference]) shows you how much heap storage is being used, the total number of segments allocated to the heap, the statistics for the optional heap pools algorithm, and the recommended values for the HEAP, ANYHEAP, BELOWHEAP and
HEAPPOOLS run-time options. For PL/I multitasking applications, the Language Environment THREADHEAP run-time option can be used to tune heap storage at the task level.

The heap pools algorithm (see "Using HEAPPOOLS to improve performance" on page 173) can be used to significantly increase the performance of heap storage allocation, especially in a multi-threaded application that experiences contention for heap storage. However, if the algorithm is not properly tuned, heap storage could be used inefficiently.

Tuning the heap pools algorithm for an application is a three step process:

1. Run your application with the run-time options HEAPPOOLS(ON) (using the default cell sizes and percentages) and RPTSTG(ON) for some time with a representative application workload. Then examine the "HEAPPOOLS Statistics" and "HEAPPOOLS Summary" sections of the "Storage Report for Enclave" report.

2. Change the cell sizes in the HEAPPOOLS run-time option to the "Suggested Cell Sizes" from the first run. Re-run the application with a representative workload, using the default percentages in the HEAPPOOLS option. Examine the storage report.

3. The values listed as "Suggested Percentages for current Cell Sizes" should be the optimal values to minimize storage use.

Any time there is a significant change in the workload, repeat these tuning steps to obtain optimal HEAPPOOLS values.

RPTSTG(ON) and the STORAGE run-time option (see z/OS Language Environment Programming Reference) can have a negative affect on the performance of your application. Therefore, always use the IBM-supplied default setting RPTSTG(OFF) when running production jobs. Use RPTSTG(ON) and STORAGE(NONE,NONE,NONE) only to debug applications.

### Storage performance considerations

Use the RPTSTG(ON) option to generate a report about the amount of storage your application uses in various Language Environment storage classes (such as STACK, THREADSTACK, LIBSTACK, THREADHEAP, HEAP, HEAPPOOLS and BELOWHEAP). You can also use the report to determine your application’s minimum storage requirements and the number of segments allocated and freed, and the manner in which heap pool cells are being used. You can use this information to tune your application to minimize the number of segments allocated and freed, and to increase the efficiency of the heap pools algorithm. Before putting your application into production, be sure to specify the RPTSTG(OFF) option so that no storage report is generated. RPTSTG(ON) can have a negative affect on the performance of your application, because as the application runs, statistics are kept on storage requests.

### Dynamic storage services

Language Environment provides callable services that let you get and free heap storage at selected points in your application. Stack storage is automatically allocated upon entry into a routine and freed upon exit, but you must allocate heap storage, which persists until you free it or until your application terminates.
Stack and Heap Storage

Each time your application runs, the setting of the HEAP run-time option specifies the size of an initial heap from which heap storage is allocated. You can allocate storage out of this initial heap whenever your application requires it. Call CEEGTST (Get Heap Storage) and specify an ID identifying the initial heap and the portion of storage in the initial heap that you require. When your application no longer requires the storage, you can call the CEEFRST (Free Heap Storage) service with the address of the element to free it.

CEECRHP (Create New Additional Heap) allows you to identify a heap, other than the initial heap, from which to get and free storage. You can use CEEGTST to allocate elements from the newly created heap. One advantage of this approach is that CEECRHP allows you to group storage elements together and to use CEEDSHP (Discard Heap) to discard them all at once when you no longer need them.

Callable services are not supported directly from a Fortran program. For information about invoking callable services from assembler routines, see [Chapter 29, "Assembler Considerations," on page 475](https://www.ibm.com/support/docview.wss?uid=swg27026133).

---

Examples of callable storage services

This section contains examples that use callable services. The first group of examples use CEEGTST and CEEFRST to build a linked list. The second group of examples use CEE3RHP, CEECRHP, CEEGTST, CEECZST, CEEFRST, and CEEDSHP to manage storage.

**C example of building a linked list**

[Figure 58 on page 177](https://www.ibm.com/support/docview.wss?uid=swg27026133) is an example of how to build a linked list in a C program using callable services.
/*Module/File Name: EDCLLST */
/******************************************************************
**FUNCTION: CEEGTST - obtain storage from user heap for a linked list.
** : CEEFRST - free linked list storage
** This example illustrates the construction of a linked list using the Language Environment storage management services.
** 1. Storage for each list element is allocated from the user heap.
** 2. The list element is initialized and appended to the list.
** 3. After three members are appended, the list traversed and the count saved in each element is displayed.
** 4. The linklist storage is freed.

User-created heap storage

Language Environment can also manage, as a heap, storage which is obtained by a C/C++ application. The following functions provide this user-created heap storage capability:

- `ucreate()` – Creates a heap using storage provided by the caller
- `umalloc()` – Allocates storage elements from the user-created heap
- `ufree()` – Returns storage elements to the user-created heap
- `uheapreport()` – Generates a storage report to assist in tuning the application’s use of the user-created heap

This allows the application more flexibility in choosing the attributes of the heap storage. For instance, the storage could be shared memory that is accessed by multiple programs.

For more information about the user-created heap functions, see \[Z/OS C/C++ Run-Time Library Reference\].

Alternative Vendor Heap Manager

Language Environment provides a mechanism such that a vendor can provide an alternative Vendor Heap Manager (VHM) that can be used by Language Environment C/C++ applications. The VHM replaces the malloc() (default operator new and default operator new [] are included), free() (default operator delete and default operator delete [] are included), calloc() and realloc() functions for non-XPLINK and XPLINK.
The VHM will not manage the following:

- CEEGTST
- CEEVGTST
- CEEFRST
- CEEVFRST
- CEECZST
- CEEVCZST
- CEEVGTBS
- additional heaps (CEECRHP)
- user created heaps (__ucreate, __umalloc, __ufree)
- ANYHEAP
- BELOWHEAP

**Using _CEE_HEAP_MANAGER to invoke the alternative Vendor Heap Manager**

This environment variable is set by the end-user or the application to indicate that the Vendor Heap Manager (VHM), identified by the *dllname*, is to be used to manage the user heap. The format of the environment variable is:

_*CEE_HEAP_MANAGER=dllname*

**Note:** This environment variable must be set using one of the following mechanisms:

- ENVAR run-time option
- Inside the file specified by the _CEE_ENVFILE environment variable

Either of these locations is before any user code gets control, meaning prior to the HLL user exit, static constructors, and/or main getting control. Setting of this environment variable once the user code has begun execution will not activate the VHM, but the value of the environment variable will be updated.
Stack and Heap Storage
Chapter 15. Language Environment Condition Handling

Introduction

This chapter outlines the Language Environment condition handling model in a POSIX(OFF) environment. It describes what constitutes a condition in Language Environment and how Language Environment supplements existing HLL condition handling methods. It also presents several condition handling scenarios to demonstrate how Language Environment condition handling works.

If you use mixed-language applications, it is especially important for you to know how Language Environment condition handling works with existing high-level language (HLL) condition handling schemes.

The chapters that follow describe in detail the steps involved in condition handling under Language Environment, HLL-specific condition handling considerations, Language Environment—POSIX signal handling interactions, and how you can communicate events that happen in a routine to another routine.

If your application is running under CICS, you should refer to the CICS-specific condition handling information, which is discussed in "Condition Handling under CICS" on page 442. If your application is running under IMS, you should refer to the IMS-specific condition handling information, which is discussed in "Condition Handling under IMS" on page 453.

Understanding the Basics

There are two main concepts of Language Environment condition handling: the stack frame-based model and the unique, 12-byte condition token that it provides to communicate information about conditions to Language Environment resources and services.

Language Environment uses stack frames to keep track of a routine’s order of execution, and the condition handlers available for each routine. This ensures that conditions can be isolated and handled precisely where they occur in a routine.

One of the most useful features of the condition handling model is the condition token: a 12-byte data type that contains information about each condition. You can use the condition token as a feedback code or to communicate with Language Environment message services. Unlike a return code, which is specific to the caller and callee of a routine, a condition token communicates between all the routines involved in an application. A condition token contains more instance-specific information about a condition than a return code does.

Language Environment supplements, but does not replace, existing HLL condition handling techniques such as C/C++ signal handlers (created using the signal() function), PL/I ON-units, and return code-based programming techniques. HLL condition handling techniques are discussed in Chapter 16, “Language Environment and HLL Condition Handling Interactions,” on page 213.

Language Environment condition handling is most beneficial when used as part of mixed-language applications because it is consistent for all applications. If you are coding in a single language, you can use the condition handling semantics of that language, but if you have any ILC applications, you need the consistency across languages that Language Environment provides.
Language Environment can respond in many ways to a condition. For example, Language Environment can invoke a condition handler, a term used to define the specific routine that actually recognizes and responds to the condition. A condition handler can be registered by the CEEHDLR (register user-written condition handler) service, or be part of the language-specific condition handling services, such as a C/C++ signal handler or a PL/I ON-unit. HLL condition handling semantics that are intrinsic to the programming language also exist; an example is the COBOL ON SIZE phrase.
### Related Options and Services

#### Run-Time Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ABPERC</strong></td>
<td>Percolates (removes from Language Environment condition handling) a single abend</td>
</tr>
<tr>
<td><strong>DEPTHCONDLMT</strong></td>
<td>Indicates how deep conditions might be nested</td>
</tr>
<tr>
<td><strong>ERRCOUNT</strong></td>
<td>Indicates how many severity 2, 3, and 4 conditions can occur before issuing an abend.</td>
</tr>
<tr>
<td><strong>TRAP</strong></td>
<td>Indicates whether Language Environment routines should handle abends and program interrupts.</td>
</tr>
<tr>
<td><strong>XUFLOW</strong></td>
<td>Indicates if exponent underflow should cause program interrupt.</td>
</tr>
</tbody>
</table>

#### Callable Services

<table>
<thead>
<tr>
<th>Service</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CEE3CIB</strong></td>
<td>Returns pointer to the condition information block that is associated with a condition token passed to a user-written condition handler</td>
</tr>
<tr>
<td><strong>CEE3GRN</strong></td>
<td>Gets name of routine that incurred the condition currently being processed</td>
</tr>
<tr>
<td><strong>CEE3GRO</strong></td>
<td>Returns the offset of the location within the most current Language Environment-conforming routine where a condition occurred</td>
</tr>
<tr>
<td><strong>CEE3SPM</strong></td>
<td>Queries or modifies (by enabling or masking) hardware conditions</td>
</tr>
<tr>
<td><strong>CEE3SRP</strong></td>
<td>Sets a resume point within user application code to resume from a Language Environment user condition handler</td>
</tr>
<tr>
<td><strong>CEEGQDT</strong></td>
<td>Retrieves q_data token from the ISI</td>
</tr>
<tr>
<td><strong>CEEHDLR</strong></td>
<td>Registers user-written condition handler</td>
</tr>
<tr>
<td><strong>CEEHDLU</strong></td>
<td>Unregisters user-written condition handler</td>
</tr>
<tr>
<td><strong>CEEITOK</strong></td>
<td>Returns the initial condition token from the current condition information block</td>
</tr>
<tr>
<td><strong>CEEMRCE</strong></td>
<td>Moves the resume cursor to an explicit location where resumption is to occur after a condition has been handled</td>
</tr>
<tr>
<td><strong>CEEMRCR</strong></td>
<td>Moves resume cursor relative to handle cursor. You might view this as performing a GOTO out of block, or setjmp() and longjmp().</td>
</tr>
<tr>
<td><strong>CEESGL</strong></td>
<td>Signals a condition</td>
</tr>
</tbody>
</table>

See [z/OS Language Environment Programming Reference](https://zos.mics.com) for more information on these options and services.
The Stack Frame Model

A stack consists of an ordered set of stack elements, called stack frames, which are managed in a last-in first-out manner. In this book, unqualified references to stack mean invocation stack. The invocation stack can contain multiple invocation stack frames, which represent invocation instances of routines. A stack frame is added to the stack on entry to a routine and removed from the stack on exit from the routine.

The Language Environment condition handling model is based on stack frames, in which condition handling can be different in different stack frames. Another condition handling model is global condition handling, which means that one condition handling mechanism remains in effect for the life of an application. The distinction between global condition handling and condition handling within a stack frame-based model can affect how a condition is handled in your application, particularly if it is a mixed-language application.

The following cause a stack frame to be added to the invocation stack:

- A function call in C or C++ that has not been inlined
- Entry into a program in COBOL
- Entry into a main program or subprogram in Fortran
- Entry into a procedure or begin block in PL/I
- Entry into an ON-unit in PL/I

A stack frame is added to the stack every time a new routine is entered and removed when it is exited. Language Environment uses stack frames to keep track of such things as the routine currently executing, the point at which an error occurs, and the point at which execution should resume after the condition is handled.

Each new stack frame can contain user-written condition handlers registered with CEEHDLR, but language-specific handlers such as C/C++ signal handlers are not associated with each stack frame. User condition handlers can be unregistered explicitly (by calling CEEHDLU) or implicitly, as when the routine that registered the handler returns control to its caller.

Two cursors, or pointers, keep track of the state of condition handling. The cursors are named the handle and resume cursors.

Handle Cursor

If a condition occurs or is raised, the handle cursor initially points to the most recently established condition handler within the stack frame. As condition handling progresses, the handle cursor moves to earlier handlers within the stack frame, or to the first handler in the calling stack frame.

Resume Cursor

The resume cursor generally points to the next sequential instruction where a routine would continue running if it were to resume. Initially, the resume cursor is positioned after the machine instruction that caused or signaled the condition. You can move the resume cursor relative to the handle cursor by calling CEEMRCP. You can use CEEMRCE to move the resume cursor to an explicit location in the application when the application resumes.
What Is a Condition in Language Environment?

Language Environment defines a condition as any event that can require the attention of a running application or the HLL routine supporting the application. A condition is also known as an exception, interrupt, or signal. Language Environment makes it possible to respond to events that in the past might have caused a routine to abend, including hardware-detected errors or operating system-detected errors.

All of the following can generate a condition in Language Environment:

**Hardware-detected errors**
Also known as program interruptions, these are signaled by the central processing unit. Examples are the fixed-overflow and addressing exceptions. The operating system derives the error codes from the codes defined for the machine on which the application is running. The error codes differ from machine to machine.

**Operating system-detected errors**
These are software errors and are reported as abends. An example is an OPEN error.

**Software-generated signals**
Signals are conditions intentionally and explicitly created by Language Environment (using CEESGL), language library routines, language constructs (such as C’s `raise()` or PL/I’s SIGNAL), or user-written condition handling routines.

Under Language Environment, an exception is the original event, such as a hardware signal, software-detected event, or user-signal event, that is a potential condition. Through the enablement step (described briefly in Steps in Condition Handling and in detail in Chapter 16, “Language Environment and HLL Condition Handling Interactions,” on page 213), Language Environment might deem an exception to be a condition, at which point it can be handled by Language Environment, user-written condition handlers, if they are present, or HLL condition handling semantics.

Steps in Condition Handling

Language Environment condition handling is performed in three distinct steps: the enablement, condition, and termination imminent steps.

During the condition and termination imminent steps, the stack is used to determine the order of condition handler processing. Condition handlers associated with the most recent stack frame added to the stack are given first chance to handle the condition. Condition handlers associated with the next stack frame are next given a chance, and so on until either the condition is handled or default Language Environment condition handling semantics take effect.

In a POSIX(OFF) environment, only routines that are currently active on the stack have an effect on condition handling. For example, in a COBOL — PL/I application, a COBOL main program calls a PL/I subroutine. The subroutine then returns control to COBOL. The PL/I routine is no longer on the stack and does not affect condition handling. See "Language Environment and POSIX Signal Handling Interactions" on page 233 for information about signal handling under z/OS UNIX.
Condition Handling Introduction

Enablement Step

*Enablement* refers to the determination that an exception should be processed as a condition. The enablement step begins at the time an exception occurs in your application. In general, you are not involved with the enablement step; Language Environment determines which exceptions should be enabled (treated as conditions) and which should be ignored, based on the languages currently active on the stack. If you do not specify explicitly or as a default any of the services or constructs discussed below, the default enablement of your HLL applies.

If Language Environment ignores an exception, the exception is not seen as a condition and does not undergo condition handling. Processing resumes at the next sequential instruction.

You can affect the enablement of exceptions in the following ways:

- Set the TRAP run-time option to handle or ignore abends and program checks. See [“TRAP Effects on the Condition Handling Process”](#) for more information.
- Specify in the assembler user exit or ABPERC run-time option an abend code or list of codes to be percolated (passed to the operating system).
  See [“Language Environment Abends and the Enablement Step”](#) on page 199 for more information.
- Disable specific conditions by doing one of the following:
  - Code a construct such as `signal(sigfpe, SIG_IGN)` in a C/C++ function or a PL/I NOZERODIVIDE prefix in a PL/I procedure to request that program checks (in this case divide-by-zero) be ignored if they occur in either routine. Execution continues at the next sequential instruction after the one that caused the divide-by-zero. Condition handlers never get a chance to handle the program check because it is not considered a condition.
  - Call the CEE3SPM callable service or use the XUFLOW run-time option to disable hardware conditions.
    See [“Using CEE3SPM and XUFLOW to Enable and Disable Hardware Conditions”](#) on page 199 for more information.

In summary, not all hardware interrupts, software conditions, or user-signaled events become conditions. Those that are not ignored do become conditions enter the condition step. See [“Condition Step”](#) on page 200 for the details of what takes place during the condition step.

**TRAP Effects on the Condition Handling Process**

The TRAP run-time option specifies how Language Environment handles abends and program interrupts; TRAP(ON,SPIE) is the IBM-supplied default. For more information about the TRAP run-time option, see [z/OS Language Environment Programming Reference](#).

When TRAP(ON,SPIE) is in effect, Language Environment is notified of abends and program interrupts. Language semantics, C/C++ signal handlers, PL/I ON-units, and user-written condition handlers can then be invoked to handle them. An exception to this behavior is that Language Environment cannot handle Sx22 abends, even if TRAP(ON) is specified.

**CEESGL and TRAP:** When a condition is raised using the CEESGL callable service, C/C++ signal handlers, PL/I ON-units, and user-written condition handlers are always invoked if present, regardless of the setting of TRAP. If none of these
handle the condition, then HLL semantics’ default action could be taken. See z/OS Language Environment Programming Reference for more information about TRAP and CEESGL.

Language Environment Abends and the Enablement Step
You can prevent Language Environment from automatically issuing abends for certain exceptions by requesting that an abend code or codes be percolated. If an abend is percolated, neither Language Environment nor an HLL can handle it; only the operating system can respond to the abend.

Abends can be percolated in two ways:
• You can specify in the assembler user exit CEEXBITA a list of abend codes that Language Environment percolates. You can specify both system abends and user abends. See Chapter 28, “Using Run-Time User Exits,” on page 457 for more information.
• The ABPERC run-time option allows you to specify which (if any) abend code should be percolated by Language Environment. ABPERC is intended for use as a debugging tool that allows the application to execute with TRAP(ON).

For a list of Language Environment-issued abends and information about using ABPERC to debug your application, see z/OS Language Environment Run-Time Messages and z/OS Language Environment Debugging Guide. See z/OS Language Environment Programming Reference for more information about the TRAP and ABPERC run-time options.

Using CEE3SPM and XUFLOW to Enable and Disable Hardware Conditions
You can change the enablement of certain hardware interrupts using the CEE3SPM callable service and XUFLOW run-time option under Language Environment (see z/OS Language Environment Programming Reference for syntax).

Language Environment provides the CEE3SPM callable service to replace assembler language routines that manipulate bits 20 through 23 of the Program Status Word (PSW) to enable or disable the following hardware interrupts:
• Decimal overflow
• Exponent underflow
• Fixed-point overflow
• Significance

The XUFLOW run-time option specifies whether an exponent underflow exception causes a program interrupt. Both CEE3SPM and XUFLOW can change the condition handling semantics of the HLL or HLLs of your application. Therefore, use CEE3SPM and XUFLOW only if you understand the effect they have on your application.

C and C++ Considerations: C and C++ ignore requests to enable the decimal overflow, exponent underflow, fixed-point overflow, or significance exceptions.

COBOL Considerations: The decimal overflow and fixed-point overflow exceptions cannot be enabled in a COBOL program; COBOL ignores any request to enable these exceptions.

Fortran Considerations: The fixed-point overflow, decimal overflow, and exponent underflow masks are ON by default. Mask settings remain in effect until changed by CEE3SPM or XUFLOW, or until the application calls a new load module containing code from a language that specifies the masks ON.
Condition Handling Introduction

The Fortran XUFLOW callable service can affect the semantics of any ILC application or any program setting made with CEE3SPM.

**PL/I Considerations:** PL/I semantics depend on the program mask being given certain settings:
- The fixed-point overflow, decimal overflow, and exponent underflow masks are ON. For VisualAge PL/I, the fixed-point overflow mask is OFF.
- The significance mask is OFF.

Condition Step

The condition step begins after the enablement step has completed and Language Environment determines that an exception in your application should be handled as a condition. In the simplest form of this step, Language Environment traverses the stack beginning with the stack frame for the routine in which the condition occurred and progresses towards earlier stack frames. Condition handlers are invoked at each intervening stack frame and given a chance to respond in any of the ways described in "Responses to Conditions" on page 206. The condition step lasts until a condition handler requests a resume or until default condition handling occurs (condition went unhandled). Throughout the following discussion, refer to [Figure 64](#)

![Figure 64. Condition Processing](#)

1. Language Environment condition handling begins at the most recently activated stack frame. This is the stack frame associated with the routine that incurred the condition. In [Figure 64](#), this is A, or routine 4.
2. If the debug tool is present, and the setting of the TEST run-time option indicates that it should be given control, it is invoked. See [z/OS Language Environment Programming Reference](#) for information about the TEST run-time option.
3. If the debug tool is not invoked, or does not handle the condition, Language Environment traverses the stack, stack frame by stack frame, towards earlier stack frames. This is in the direction of arrow B in [Figure 64](#). User-written condition handlers established using CEEHDLR, and then language-specific condition handlers present at each stack frame such as C/C++ signal handlers or PL/I ON-units, can all respond by percolating, promoting, or handling the condition (see "Responses to Conditions" on page 206 for a discussion of these actions).
4. Condition handling is complete if one of the handlers requests the application to resume execution. If all stack frames have been visited, and no condition handler has requested a resume, the language of the routine in which the exception occurred can enforce default condition handling semantics.
Condition Handling Introduction

5. If the HLL of the routine that originated the condition does not issue a resume, what occurs next depends on whether there is a PL/I routine active on the stack.

   a. The condition is percolated if there is no currently active PL/I routine or if the condition is not one that PL/I promotes to the ERROR condition (see "Promoting Conditions to the PL/I ERROR Condition" on page 229 for details). Language Environment default actions are then taken based on the severity of the unhandled condition, as indicated in Table 32 on page 202. If the condition is of severity 2 or above, Language Environment promotes the condition to T_I_U (termination imminent due to an unhandled condition) and returns to routine 4 to redrive the stack (this occurs at points C and D in Figure 64 on page 200). For more information about the termination imminent step and T_I_U, see "Termination Imminent Step" on page 202.

   b. If the condition is one that PL/I promotes to the PL/I ERROR condition (see "Promoting Conditions to the PL/I ERROR Condition" on page 229 for details), the condition is promoted at the location represented as C in Figure 64 on page 200 and another pass is made of the stack. The following takes place:

      - On the next pass of the stack (D), any ERROR ON-unit or user-written condition handler is invoked. If the ON-unit or user-written condition handler issues a resume, condition handling ends. Execution resumes where the resume cursor points.

      - If no ON-unit or user-written condition handler issues a resume, the ERROR condition is promoted (at E) to T_I_U. (See "Processing the T_I_U Condition" on page 203 for a discussion of T_I_U.)

      - A final pass of the stack is made, beginning in Routine 4 where the original condition occurred (F). Because T_I_U maps to the PL/I FINISH condition, both established PL/I FINISH ON-units and user-written condition handlers registered for T_I_U are invoked.

      - If no user-written or HLL condition handlers act on the condition, Language Environment begins thread termination activities in response to the unhandled condition (G). See Table 32 on page 202 for the default actions that Language Environment takes for conditions of different severities.

Influencing Condition Handling with the ERRCOUNT Run-Time Option
The ERRCOUNT option allows you to specify the number of errors that are tolerated during the execution of a thread. Each condition of severity 2 or above, regardless of its origin, increments the error count by one. POSIX conditions are not counted. If the error count exceeds the limit, Language Environment terminates the enclave with abend code 4091 and reason code 11.

See z/OS Language Environment Programming Reference for syntax and more information on using ERRCOUNT.
**Condition Handling Introduction**

Table 32. Language Environment Default Responses to Unhandled Conditions. Language Environment’s default responses to unhandled conditions fall into one of two types, depending on whether the condition was signaled using CEESGL and an fc parameter, or the condition came from any other source.

<table>
<thead>
<tr>
<th>Severity of Condition</th>
<th>Condition Signaled by User in a Call to CEESGL with an fc</th>
<th>Condition Came from Any Other Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 (Informative message)</td>
<td>Return CEE069 condition token, and resume processing at the next sequential instruction. See the fc table for CEESGL <a href="https://www.ibm.com">Z/OS Language Environment Programming Reference</a> for a description of the CEE069 condition token.</td>
<td>Resume without issuing message.</td>
</tr>
<tr>
<td>1 (Warning Message)</td>
<td>Return CEE069 condition token, and resume processing at the next sequential instruction.</td>
<td>If the condition occurred in a stack frame associated with a COBOL program, resume and issue the message. If the condition occurred in a stack frame associated with a non-COBOL routine, resume without issuing message.</td>
</tr>
<tr>
<td>2 (Program terminated in error)</td>
<td>Return CEE069 condition token, and resume processing at the next sequential instruction.</td>
<td>Promote condition to T_I_U, redrive the stack, then terminate the thread if the condition remains unhandled. Message issued if TERMTHDACT(MSG) is specified. See &quot;Processing the T_I_U Condition&quot; on page 203 for more information on T_I_U.</td>
</tr>
<tr>
<td>3 (Program terminated in severe error)</td>
<td>Return CEE069 condition token, and resume processing at the next sequential instruction.</td>
<td>Promote condition to T_I_U, redrive the stack, then terminate the thread if the condition remains unhandled. Message issued if TERMTHDACT(MSG) is specified.</td>
</tr>
<tr>
<td>4 (Program terminated in critical error)</td>
<td>Promote condition to T_I_U, redrive the stack, then terminate the thread if the condition remains unhandled. Message issued if TERMTHDACT(MSG) is specified.</td>
<td>Promote condition to T_I_U, redrive the stack, then terminate the thread if the condition remains unhandled. Message issued if TERMTHDACT(MSG) is specified.</td>
</tr>
</tbody>
</table>

**Termination Imminent Step**

The termination imminent step occurs for certain unhandled conditions or as the result of STOP-like language constructs such as C/C++ exit() or abort(); Fortran STOP statement or a call to EXIT, SYSRCX, or DUMP; or PL/I STOP. The termination imminent step occurs when one of the following events occurs:

- The T_I_U condition (Termination Imminent due to Unhandled condition) is raised
- The T_I_S condition (Termination Imminent due to Stop) is raised to indicate that the thread can potentially terminate

When T_I_U or T_I_S is raised, another pass is made of the stack. See "Processing the T_I_U Condition" on page 203 and "Processing the T_I_S Condition" on page 203 for details on what can happen during and after the pass.

You can directly signal T_I_U and T_I_S using the CEESGL callable service. When you do, Language Environment behaves as described in "CEESGL and the Termination Imminent Step" on page 205.
Condition Handling Introduction

Processing the T_I_U Condition

Table 32 on page 202 indicates that for severity 4 conditions signaled by CEESGL, and for severity 2 and above conditions that remain unhandled after all condition handlers have had a chance to handle them, Language Environment promotes the unhandled condition to T_I_U. See z/OS Language Environment Programming Reference for a discussion of CEESGL. T_I_U is a severity 3 condition with the representation shown in Table 33.

Table 33. T_I_U Condition Representation

<table>
<thead>
<tr>
<th>Symbolic Feedback Code (fc)</th>
<th>Severity</th>
<th>Message Number</th>
<th>Message Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE066</td>
<td>3</td>
<td>0198</td>
<td>Termination of a thread was signaled.</td>
</tr>
</tbody>
</table>

After promoting the condition to T_I_U, Language Environment does the following:

1. Language Environment revisits each stack frame on the stack, beginning with the stack frame in which the condition occurred, and progressing towards earlier stack frames. At each stack frame, HLL and user-written condition handlers are given a chance to handle the condition.

   The T_I_U condition maps to the PL/I FINISH condition. Therefore, an established PL/I FINISH ON-unit or registered user-written condition handler can be invoked to handle the condition. After the ON-unit or condition handler completes its processing, the termination activities described in Step 3 take place.

2. If, during the course of condition handling, the resume cursor is moved and a resume is requested by a condition handler, execution resumes at the instruction pointed to by the resume cursor. If a resume is requested for the T_I_U condition without moving the resume cursor, the thread terminates immediately with no clean-up. See z/OS Language Environment Programming Reference for a discussion of the CEEMRCH service.

3. If all stack frames have been visited, and the condition remains unhandled, or a FINISH ON-unit or user-written condition handler has processed the condition and returned, Language Environment performs the following termination activities:
   • Sets the reason and return codes. The return code value is based on the severity of the original unhandled condition, not on the T_I_U condition (which is a severity 3).
   • Issues a message for the condition.
   • Prints a traceback and dump depending on the setting of the TERMTHDICT run-time option (see z/OS Language Environment Programming Reference for syntax)
   • Terminates the thread.

   In this release of Language Environment, multithreading is supported only in a POSIX(ON) environment. Unless your application is doing multithreading, therefore, when a thread terminates, the entire enclave terminates.

Processing the T_I_S Condition

The termination imminent step of condition handling can also be entered as the result of the T_I_S (Termination Imminent due to STOP) condition being signaled. T_I_S is a severity 1 condition with the following representation:
Condition Handling Introduction

The T_I_S condition is raised by Language Environment immediately upon detection of a language STOP-like construct such as:

- C/C++ `exit()` function
- COBOL STOP RUN
- Fortran STOP statement
- Fortran END statement in a main program
- PL/I EXIT statement
- PL/I STOP statement

The HLL constructs listed above initiate termination activities for the enclave in two steps:

1. Language Environment traverses the stack beginning at the stack frame for the routine containing the STOP-like statement and proceeds, stack frame by stack frame, towards earlier stack frames. User-written and HLL condition handlers at each stack frame are given a chance to handle the condition.

   T_I_S maps to the PL/I FINISH condition. Therefore, both established PL/I FINISH ON-units and user-written condition handlers can be invoked. After the ON-unit or condition handler completes its processing, the termination activities described in Step 2 take place.

2. If all stack frames have been visited, and the condition remains unhandled, or an ON-unit or condition handler has processed the condition and returned, Language Environment:
   - Sets the reason and return codes
   - Terminates the thread

   Language Environment performs only one pass of the stack for STOP-like statements.

Termination Imminent Step and the TERMTHDACT Run-Time Option

You can use the TERMTHDACT run-time option to set the type of information you receive after your application terminates in response to a severity 2, 3, or 4 condition. For example, you can specify that a message or dump is to be generated if the application terminates.

TERMTHDACT behavior under z/OS UNIX differs slightly; for details, see “Termination Imminent Step under z/OS UNIX” on page 236.

**PL/I Considerations:** For those PL/I conditions that do not raise the ERROR condition as part of their implicit action, PL/I requires that a message be issued. For these conditions, the message is issued regardless of the setting of TERMTHDACT. Therefore, messages can be delivered even when TERMTHDACT(QUIET) is set.

If the condition remains unhandled (for example, the PL/I FINISH condition is still regarded as unhandled after normal return from a FINISH ON-unit), and the application terminates, the message associated with the condition is not issued again at termination.
Invoking Condition Handlers

After a condition has been enabled, Language Environment steps through the stack and passes control to the most recently established condition handling routines in the stack. Condition handling routines can be in the form of the Debug Tool, a user-written condition handler, or a language-specific condition handling mechanism:

Debug Tool

If you have invoked a debug tool using the TEST run-time option or the CEETEST callable service (see z/OS Language Environment Programming Reference), the debug tool gains control when a condition occurs. Unless a condition is promoted and is passed through the stack again for additional condition handling, a debug tool is invoked only once per stack.

User-Written Condition Handler

User-written condition handlers are routines that you supply to handle specific conditions that might arise in the run-time environment. As shown in Figure 65 on page 206 a LIFO queue containing zero or more user-written condition handlers is associated with each stack frame. A different queue exists for each stack frame. For example, if routine A calls routine B, there is a new queue associated with the stack frame for routine B.
User-written condition handlers are registered on a stack frame-by-stack frame basis using the CEEHDLR callable service. A call to CEEHDLR from a given routine adds a user-written condition handler onto the queue for the stack frame associated with that routine. Registering a condition handling routine using CEEHDLR implicitly requests Language Environment to pass control to this routine when a condition occurs. For example, you could call CEEHDLR to register two user-written condition handlers for the same stack frame, one that handles floating-point underflow conditions and another that handles floating-point divide conditions.

The most recent user condition handler registered using CEEHDLR is the first to be invoked by Language Environment. Note that you could also register a single user condition handler to handle both of these conditions.

The user-written condition handlers can respond to a condition in any of the ways described in "Responses to Conditions."

User-written condition handlers are given a chance to handle a given condition before the language-specific condition handling semantics described below take effect.

**Language-Specific Condition Handling Semantics**

If language-specific semantics are established within a stack frame, they are honored. Of course, the language-specific handling mechanisms act only on those conditions for which the language has a defined action. The language *percolates* all other conditions by passing them on to the next condition handler.

If a condition is unhandled after the stack is traversed, default language-specific and Language Environment condition semantics take over.

**Responses to Conditions**

Condition handlers are routines written to respond to conditions in one of the following ways:
Condition Handling Introduction

Resume
A resume occurs when a condition handler determines that the condition was handled and normal application execution should resume. A program resumes running usually at the instruction immediately following the point where the condition occurred.

A resume cursor points to the place where a routine should resume. The resume cursor can be manipulated to be placed at a specific point by using the CEEMRCR (move resume cursor) callable service (see z/OS Language Environment Programming Reference).

Percolate
A condition is percolated if a condition handler declines to handle it. User-written condition handlers, for example, can be written to act on a particular condition, but percolate all other conditions. Language Environment can continue condition handling in one of the following places:

- With the next condition handler associated with the current stack frame. This can be either the first condition handler in a queue of user-established condition handlers, or the language-specific condition semantics.
- With the most recently established condition handler associated with the calling stack frame.

Promote
A condition is promoted when a condition handler converts the condition into one with a different meaning. A condition handler can promote a condition for a variety of reasons, including the condition handler’s knowledge or lack of knowledge about the cause of the original condition. A condition can be promoted to simulate conditions that would normally come from a different source.

Fix-up and Resume
The qualifying data is modified and a resume occurs with a corrective action. There are several possible responses that can be applied:

**resume with new input value**
A new input value is specified and the failing operation is tried again. The condition token for this action has the condition name CEE0CE.

**resume with new output value**
The program continues using a specified result in the place of what the failing operation would have provided. The condition token for this action has the condition name CEE0CF.

For more information about how these responses can be used in developing user-written condition handlers, see “User-written condition handler interface” on page 238.

Condition Handling Scenarios

The following condition handling scenarios can help you better understand what occurs during the condition handling steps. The scenarios differ in complexity, with Scenario 1 being the easiest to understand.

See Chapter 16, “Language Environment and HLL Condition Handling Interactions,” on page 213 if you are interested in specific HLL condition handling behavior.
Condition Handling Introduction

Scenario 1: Simple Condition Handling

Refer to Figure 66 throughout the following discussion.

Figure 66. Scenario 1: Division by Zero with No User Condition Handlers Present

In this scenario, no C/C++ handlers created by a call to signal(), PL/I ON-units, or user-written condition handlers registered using the CEEHDLR service are established at any stack frame in the application.

1. A divide-by-zero exception occurs in routine B.
2. The divide-by-zero exception is enabled by the language of the stack frame in which it occurred because it is a problem that, if it remains unhandled, causes termination.
3. The following occurs in the condition step:
   - If any user-written condition handlers have been registered using the CEEHDLR callable service on the routine B’s stack frame, they are given control. No handlers have been registered, so the condition is percolated.
   - If a C/C++ signal handler is registered, or if a PL/I ON-unit is established on the stack frame, it is given control. Neither one exists on routine B’s stack frame, so the condition is percolated.
   - If any user-written condition handlers have been registered using CEEHDLR on routine A’s stack frame, they are given control. No handlers have been registered, so the condition is percolated.
   - If a C/C++ signal handler is registered or if a PL/I ON-unit is established on routine A’s stack frame, it is given control. No C/C++ signal handler or PL/I ON-unit has been established for the stack frame, so the condition is percolated.
   - After the oldest stack frame (in this case, that for routine A) has been checked, HLL and Language Environment default actions occur. Assume that the HLL percolates the condition to Language Environment. Language Environment examines the severity of the unhandled divide-by-zero condition (severity 3), promotes the condition to T_I_U, and requests that the stack be redriven. This is the end of the condition step and the beginning of the termination imminent step.
4. The following occurs during the termination imminent step:
   - The stack frame for routine B is revisited, and if a user-written condition handler is present, it is given control. No handlers are registered, so T_I_U is percolated.
   - If a C/C++ signal handler or PL/I ON-unit can respond to the T_I_U condition, it is given control. In this case, there are none, so the condition is percolated.
The stack frame for routine A is revisited, and checked for user-written condition handlers registered for the T.I.U condition, C/C++ signal handlers or PL/I ON-units. No handlers are registered, so T.I.U is percolated.

- Language Environment takes the default action for the unhandled T.I.U condition, which terminates the enclave.

**Scenario 2: User-Written Condition Handler Present for T.I.U**

Scenario 2 is much the same as Scenario 1, except that routine A does have a user-written condition handler established. Refer to Figure 67 throughout the following scenario.

![Figure 67. Scenario 2: Division by Zero with a User-Written Condition Handler Present in Routine A](image)

In this scenario, routine A is a routine that invokes other prewritten applications. If any of the components of the prewritten application fail, routine A must remain up and take alternate action. Therefore, routine A has a user-written condition handler registered. The handler is designed to handle the T.I.U condition by issuing a nonlocal jump to a location within routine A. The handler percolates all conditions other than T.I.U.

1. A divide-by-zero exception occurs in routine B.
2. The divide-by-zero exception is enabled by the language of the stack frame in which it occurred because it is a problem that, if it remains unhandled, causes termination.
3. The following occurs in the condition step:
   - If a user-written condition handler has been registered for the divide-by-zero condition on routine B’s stack frame, it is given control. One has not been registered, so the condition is percolated.
   - If a C/C++ signal handler has been registered or a PL/I ON-unit has been established for the divide-by-zero condition, it is given control. No C/C++ signal handler or ON-unit is present, so the condition is percolated to Language Environment.
   - If a user-written condition handler has been registered on routine A’s stack frame, it is given control. However, because the divide-by-zero condition is not the one the handler is looking for, the condition is percolated.
   - If a C/C++ signal handler is registered or a PL/I ON-unit is established for the condition on routine A’s stack frame, it is given control. Neither one is present, so the condition is percolated.
Condition Handling Introduction

- After the earliest stack frame (in this case, that for routine A) has been checked, HLL and Language Environment default actions occur. In this case, assume that the HLL percolates the condition to Language Environment. Language Environment examines the severity of the unhandled divide-by-zero condition (severity 3), promotes the condition to T_I_U, and requests that the stack be redriven. This is the end of the condition step and the beginning of the termination imminent step.

4. The following occurs during the termination imminent step:
   - Language Environment revisits the stack frame for routine B, checking for user-written condition handlers registered for the T_I_U condition. No handlers are registered, so T_I_U is percolated.
   - If a PL/I FINISH ON-unit is present, it is given control. In this example, there isn’t one, so the condition is percolated.
   - Language Environment revisits the stack frames for routine A, checking for user-written condition handlers registered for the T_I_U condition. There is one, it is given control. The user code in the handler, using either HLL or Language Environment facilities, causes control to pass to a location within routine A.

5. Control resumes with routine A at the location specified. The condition is now handled.

Scenario 3: Condition Handler Present for Divide-by-Zero

Scenario 3 is much the same as scenario 2, except that routine B has a user-written condition handler established to handle the divide-by-zero condition. Refer to Figure 68 throughout the following scenario.

```
+----------------+     Divide-by_zero condition occurs here
| Routine B      |                    |
| Cond HldrB     |                    |
+----------------+     Routine A
|                  |                    |
| Routine A       |                    |
| Cond HldrA     |
```

*Figure 68. Scenario 3: Division by Zero with a User Handler Present in Routine B*

The handler established by routine B is designed to deal with divide-by-zero and possibly other conditions that occur either during its execution or in the routines that it calls. For a divide-by-zero condition, the handler is to print a message and continue processing.

1. A divide-by-zero exception occurs in routine B.
2. The divide-by-zero exception is enabled by the language of the stack frame in which it occurred because it is a problem that, if it remains unhandled, causes termination.
3. The following occurs in the condition step:
   - If a user-written condition handler has been registered using the CEEHDLR callable service on routine B’s stack frame, it is given control. The handler
recognizes the divide-by-zero as a condition it is capable of dealing with. It produces a message, does appropriate clean-up, and then causes resumption either through HLL constructs or Language Environment services.

4. The condition is now considered to be handled and is never seen by stack frame A or the Language Environment default handler.
Condition Handling Introduction
Chapter 16. Language Environment and HLL Condition Handling Interactions

This is the second part of the condition handling discussion. It would be helpful for you to read Chapter 15, “Language Environment Condition Handling Introduction,” on page 193 before reading this chapter. Chapter 15 introduces you to terminology and concepts that are discussed in the present chapter, and offers a brief overview of pre-Language Environment HLL condition handling. It discusses in detail the Language Environment condition handling model and the many services that you can use to tailor how conditions are handled in your application. In addition, it introduces the three steps of condition handling in Language Environment.

Understanding the Basics

This chapter discusses HLL condition handling semantics, focusing on how HLL semantics interact with the Language Environment condition handling model and services. C, C++, COBOL, Fortran, and PL/I are each discussed, and condition handling scenarios and examples are provided. This chapter also outlines the interactions between POSIX signal handling and Language Environment condition handling. See one of the following sections for details:

- “C Condition Handling Semantics”
- “C++ Condition Handling Semantics” on page 221
- “COBOL Condition Handling Semantics” on page 221
- “Fortran Condition Handling Semantics” on page 226
- “PL/I Condition Handling Semantics” on page 228
- “Language Environment and POSIX Signal Handling Interactions” on page 233

If you are running a single-language application written in C or PL/I, which have extensive built-in error handling functions, and you are relying entirely upon the semantics of these languages to handle errors, you will not notice much difference in how errors are handled under Language Environment.

However, if you are running a single-language application written in COBOL or assembler that has little built-in error handling, you might notice a change in how errors are handled under Language Environment. For example, in an application that relies on abend codes to handle errors, you might need to alter the assembler user exit to get the same behavior under Language Environment as under the previous run-time environment. See Chapter 28, “Using Run-Time User Exits,” on page 457 for information on modifying the assembler user exit.

For information on condition handling in ILC applications, see z/OS Language Environment Writing Interlanguage Communication Applications

C Condition Handling Semantics

This section describes C condition handling in an MVS POSIX(OFF) environment. If you run applications that contain POSIX functions, you should also read “Language Environment and POSIX Signal Handling Interactions” on page 233, which discusses the interaction between POSIX signal handling and Language Environment condition handling.

C employs a global condition handling model, which, on initialization, defines the actions that are taken when a condition is raised. The actions defined by C apply to an entire enclave, not just to a routine or block within an enclave. You can alter a
specific action that the C condition handler takes when a condition is raised, however, by coding `signal()` function calls in your applications.

C recognizes a number of errors; some correspond directly to the errors detected by the hardware or the operating system, and some are unique to C. All actions for condition handling are controlled by the contents of the C global error table. Table 35 contains default C-language error handling semantics.

Comparison of C-Language Environment Terminology

The term `signal` is defined differently under C than under Language Environment, and you need to know the distinction to understand how C and Language Environment condition handling interact. Here is a comparison of the terminology Language Environment and C use to describe the same general idea:

- Using Language Environment services, you `register` a condition handler by using CEEHDLR, and you `raise` a condition by using CEESGL.
- Using C functions, you `register` a signal handler by using the `signal()` function, and you `raise` a signal using the `raise()` function.

You can think of `signal` as the C term for a Language Environment `condition`. To simplify the following discussion, the term `condition` is used in place of `signal`. 
C signal handling functions are recognized in C++ applications. You can write a condition handling routine in C++ using C signal() and raise() functions. C++-unique exception handling functions are discussed in "C++ Condition Handling Semantics" on page 221.

Controlling Condition Handling in C

In C, conditions can come from two main sources:

- An exception might occur because of an error in the code. The exception might or might not be seen as a condition, depending on how you use the signal() function.
- You can explicitly report a condition by using the raise() function.

Using the signal() Function

The C signal() function call alters the actions that the global error table specifies will be taken for a given condition. You can use signal() to do the following:

- Ignore the condition completely. You do this by specifying signal(sig_num, SIG_IGN), where sig_num represents the condition to be ignored. When the action for the condition is to ignore it, the condition is considered to be disabled. The condition will therefore not be seen.

  Note: Exceptions to this rule are the SIGABND condition and the system or user abend represented by Language Environment message number 3250. These are never ignored, even if you specify SIG_IGN in a call to signal().

- Reset condition handling to the defaults shown in Table 35 on page 214. Actions for handling a condition are implicitly reset to the system default when the condition is reported, but at times you need to explicitly reset condition handling. Specify signal(sig_num, SIG_DFL), where sig_num is the condition to be reset.

- Call a signal handler to handle the condition. Specify signal(sig_num, sig_handler), where sig_num represents the condition to be handled, and sig_handler represents a pointer to the user-written function that is called when the condition occurs. The signal handler specified in signal() is given a chance to handle a condition only after any user-written handler established using CEEHDLR is invoked.

Using the raise() Function

When the C raise() function is called for any of the conditions listed in Table 35 on page 214, a corresponding Language Environment condition is automatically raised by a call to the CEESGL callable service. Any of these conditions (EDC6000 through EDC6004) can be handled by a user-written condition handler registered using the CEEHDLR service. For detailed descriptions of conditions EDC6000 through EDC6004, see z/OS C/C++ Programming Guide and z/OS Language Environment Run-Time Messages.

For more information about the CEEHDLR and CEESGL callable services, see z/OS Language Environment Programming Reference. For more information about using the raise() function, see z/OS C/C++ Run-Time Library Reference.

C atexit() Considerations

In all C applications, the atexit list is honored only after all condition handling activity has taken place and all user code is removed from the stack, which invalidates any jump buffer previously established.
Condition Handling Interactions

With C, you can register a number of routines that gain control during the termination of an enclave. When using the C atexit() function, consider the following:

- A C atexit routine can nominate only C routines, but those routines can call routines written in other languages.
- User-written condition handlers can be registered while running an atexit routine. However, any jump buffers established are invalid.
- If a severity 2 or greater condition arises while running an atexit routine and it is unhandled, further atexit routines are skipped and the Language Environment environment is terminated.
- A C exit() function or PL/I STOP or EXIT statement issued within an atexit routine halts all other atexit functions.
- If, while running an atexit routine, an attempt to register another atexit routine is made, the registration is ignored. The atexit routine returns a nonzero result indicating a failure to register the routine.

C++ supports atexit(), but any function pointer input to atexit() must be declared as having extern "C" linkage.

C Condition Handling Actions

In this section the condition handling semantics of C-only applications are described as they relate to the Language Environment condition handling model. Condition handling for applications with both C and non-C routines is discussed in Z/OS Language Environment Writing Interlanguage Communication Applications.

If an exception occurs while a C routine is executing, the following activities are performed:

1. The Language Environment enablement step of condition handling is entered.
   If the action defined for the exception is to ignore it for one of the following reasons, the condition is disabled. Execution continues at the next sequential instruction after the point where the condition occurred.
   - You have specified SIG_IGN in a call to the signal() function for any C condition except SIGABND or the system or user abend represented by the Language Environment message number 3250.
   - The exception is one of those listed as masked in Table 35 on page 214.
   - You did not specify any action, but the default action for the condition is SIG_IGN (see Table 35 on page 214).
   - You are running under CICS and a CICS handler is pending.

2. If SIG_IGN is not specified or defaulted for the exception, and the exception is not masked, the Language Environment condition step of condition handling is entered. These activities then occur:
   - If the debug tool is present, and the setting of the TEST run-time option indicates that it should be given control, it is invoked. See Z/OS Language Environment Programming Reference for information about the TEST run-time option.
   - If the debug tool is not invoked, or does not handle the condition, any user-written condition handlers registered using CEEHDLR for that stack frame are invoked.
   - If no user-written condition handlers are registered for the condition that has occurred, and if you have registered a signal handler for the condition, that handler is invoked.
Condition Handling Interactions

- If the signal handler handles the condition, control returns to the routine in which the condition occurred. If the signal handler cannot handle the condition, it might force termination by issuing `exit()` or `abort()`, or might issue a `longjmp()`. Condition handling can only continue after a signal handler gains control if you specify `SIG_DFL` in a call to `signal()`. If you do, the condition is percolated to the next user-written condition handler registered using CEEHDLR, or to the language-specific condition handler associated with the next stack frame.

- If condition handlers at every stack frame have had a chance to respond to the condition and it still remains unhandled, the Language Environment default actions described in Table 32 on page 202 take place.

- If the Language Environment default action is to promote the condition to T_I_U (Termination Imminent due to an Unhandled condition), the termination imminent step of condition handling is entered.

3. When the condition is promoted to T_I_U, Language Environment makes another pass of the stack looking for user-written condition handlers registered for T_I_U.

If, on the next pass of the stack, no condition handler issued a resume or moved the resume cursor, Language Environment terminates the enclave.

C Condition Handling Examples

The following sections describe various scenarios of condition handling.

**Condition Occurs with No Signal Handler Present:** The following three figures illustrate how a condition such as a divide-by-zero is handled in a C routine in Language Environment if you do not use any Language Environment callable services, or don’t have any user-written condition handlers registered.

There is no user-written condition handler or signal handler registered for C370C or any of the other C routines, so the condition is percolated through all of the stack frames on the stack. At this point, C default actions take place of percolating the condition to Language Environment. Language Environment takes its default action for an unhandled severity 3 condition and terminates the application. A message, trace, Language Environment dump, or a user address space dump could be generated depending on the setting of TERMTHDACT (see [z/OS Language Environment Programming Reference](https://www.ibm.com/servers/resourcelink/zos/language_enviroment/index.html)).

[Figure 69 on page 218](https://www.ibm.com/servers/resourcelink/zos/language_enviroment/index.html) is a C main routine that calls C370B, a subroutine that passes data to another subroutine, C370C.
/*Module/File Name: EDCMLTA */
/******************************************************************/
/* Demonstrate a failing C/370 program */
/* with multiple active routines */
/* on the stack. The call sequence is as follows: */
/* C370A --> C370B --> C370C (which does a divide-by-zero) */
/******************************************************************/

#include <stdio.h>
int y = 0;
void C370B(void);

int main(void) {
    printf("In Program C370A\n");
    C370B();
}

Figure 69. C370A Routine

/*Module/File Name: EDCMLTB */
/******************************************************************/
/* This routine is called to pass data forward to C370C. */
/* C370C will then cause a zero divide. */
/******************************************************************/

#include <stdio.h>
extern int y;
void C370C(int);

void C370B(void) {
    int x;
    printf("In Program C370B\n");
    x = y;
    C370C(x);
}

Figure 70. C370B Routine

[Figure 70 on page 219] generates a divide-by-zero. The divide-by-zero condition is percolated back to C370B, to C370A, and to Language Environment default behavior.
Condition Occurs with Signal Handler Present: Figure 72 contains a simple example of a C application in which \( y = \frac{a}{b} \) is a mathematical operation. signal (SIGFPE, c_handler) is a signal invocation that registers the routine c_handler() and gives it control if a floating-point divide exception occurs.

```c
#include <stdio.h>

#include <signal.h>

#ifdef __cplusplus
extern "C"
{ 

#endif

void c_handler(int);

#ifdef __cplusplus
}
#endif

int main(void)
{ 
  int a=8, b=0, y;
  /* */
  . *
  . */
  signal (SIGFPE, c_handler);
  /* */
  . *
  y = a/b;
  /* */
  . */
}

void c_handler(int i)
{ 
  printf("handled SIGFPE\n");
  /* */
  . */
  return;
}
```

Figure 72. C Condition Handling Example
Condition Handling Interactions

If \( b = 0 \), a floating-point divide condition occurs. Language Environment condition handling begins:

- The enablement step occurs.
  - If Table 35 on page 214 indicates that floating-point divide is a masked exception, the exception is ignored. The floating-point divide is not a masked exception, however.
  - If SIG_IGN is specified for the SIGFPE exception in any of the three examples, then the SIGFPE exception is ignored. However, this does not occur.

The floating-point divide condition is enabled and enters the condition step of condition handling.

- If a debug tool is present, it receives control.
- If a user-written condition handler is registered by CEEHDLR for that stack frame, it receives control.

If none of the above takes place, the condition manager gives the C signal-handler control. This handler in turn invokes \( \text{c_handler()} \) as specified in the \( \text{signal()} \) function in Figure 72 on page 219. Control is then returned to the instruction following the one that caused the condition.

C Signal Representation of S/370 Exceptions

S/370™ exceptions and abends are mapped to C signals. Therefore, if both of the following condition are true, you can apply C signal handling functions to S/370 exceptions and abends:

- You have set the TRAP(ON,SPIE) or the TRAP(ON,NOSPIE) run-time option (Language Environment condition handling is enabled)
- You do not request in the assembler user exit or in the ABPERC run-time option that any of the abends be percolated (ABPERC(NONE))

C signal representations for the following exceptions are provided in this section:

- For S/370 exceptions generated by the hardware or math library, see Table 36. Some of the exceptions listed in the table can be masked off for normal Language Environment execution.
- For abends, see Table 37 on page 221.

C++ Condition Handling Semantics

C++ includes the C condition handling model and new C++ constructs throw, try, and catch. For more information on these C++ constructs, see [z/OS C/C++ Language Reference]. If you use C exception handling constructs (signal/raise) in your C++ routine, condition handling will proceed as described in "C Condition Handling Semantics" on page 213. You can use C or C++ condition handling constructs in your C++ applications, but do not mix C constructs with C++ constructs in the same application because undefined behavior could result.

If you use C exception handling, a C++ routine can register a signal handler by coding signal() to handle exceptions raised in either a C or a C++ routine. If you use the C++ exception handling model, only C++ routines can catch a thrown object. When a thrown object is handled by a catch clause, execution will continue after the catch clause in the routine. If a thrown object goes unhandled after each stack frame has had a chance to handle it, C++ defines that the terminate() function is called. By default, terminate() calls abort(). You can call the C++ library function set_terminate() to register your own function to be called by terminate. When terminate() finishes calling the user's function, it will call abort().

C routines do not support try, throw, and catch, nor can C routines use signal() to register a handler for thrown objects. A C++ routine cannot register a handler via signal() to catch thrown objects; it must use catch clauses. try, throw, and catch cannot handle hardware exceptions, nor C, COBOL, PL/I, or Language Environment exceptions.

COBOL Condition Handling Semantics

COBOL native condition handling is very different from C, PL/I, or Fortran native condition handling.

COBOL provides some condition handling on a statement-by-statement basis; for example, the ON EXCEPTION phrase of the CALL statement, the ON EXCEPTION phrase of the INVOKE statement, and the ON SIZE ERROR phrase of the
Condition Handling Interactions

COMPUTE statement. For other conditions, COBOL generally reports the error. An assembler user exit is available for COBOL to specify events that should cause an abend.

For more information about user exits, see Chapter 28, “Using Run-Time User Exits,” on page 457. For a discussion of COBOL condition handling in an ILC application, see z/OS Language Environment Writing Interlanguage Communication Applications. The following discussion applies to stacks comprised solely of COBOL programs.

If an exception occurs in a COBOL program, COBOL does nothing until every condition handler at every stack frame has been interrogated.

After all stack frames have been visited, COBOL does the following:
1. Checks to see if the condition has a facility ID of IGZ (is a COBOL-specific condition). If not, COBOL percolates the condition to the Language Environment condition manager.
2. Handles the condition based on its severity (see Table 32 on page 202 for an explanation of severity codes and their meaning under Language Environment). If the condition severity is 1, a message describing the condition is issued to the destination specified in the MSGFILE run-time option, and processing resumes in the program in which the error occurred.
   If the severity is 2 or above, COBOL percolates the condition to the Language Environment condition manager. The Language Environment default action then takes place.

COBOL Condition Handling Examples

The following examples demonstrate how conditions are handled in Language Environment if you do not use any Language Environment callable services, and do not have any user-written condition handlers registered. The COBOLA program in Figure 73 on page 223 calls COBOLB in Figure 74 on page 224, which in turn calls the COBOLC program, in Figure 75 on page 225. A divide-by-zero condition occurs in COBOLC.

The divide-by-zero is enabled as a condition, so the condition step of Language Environment condition handling is entered. There is no user-written condition handler registered for COBOLC or any of the other COBOL programs, so the condition is percolated through all of the stack frames. COBOL’s default action for the divide-by-zero condition is to percolate the condition to Language Environment. The divide-by-zero condition has a severity of 3. Language Environment’s default response to an unhandled severity 3 condition is to terminate the application and issue a message if TERMTHDACT(MSG) is specified.
Figure 73. COBOLA Program

Figure 74 on page 224 calls COBOLC and passes data to it.
Condition Handling Interactions

Figure 75 on page 225 generates a divide-by-zero condition. The divide-by-zero condition is percolated back to COBOLB, to COBOLA, and to Language Environment default behavior.

```
Resuming Execution after an IGZ Condition Occurs

When a COBOL condition with a facility ID of IGZ occurs, you must call CEEMRCR with a 0 or 1 type_of_move before a resume is attempted. You cannot resume in place after an IGZ condition occurs because the current stack frame is that for the run-time library routine. If a user-written condition handler issued a result_code 10 (see "User-written condition handler interface" on page 238) without moving the resume cursor first, that would be a resume in place. A 0 type_of_move results in a resume at the instruction in the program following the call to the COBOL run-time library routine. For example, if you encounter an error when trying to open a file, you cannot resume in place. You must either move the resume cursor and then resume, or percolate the condition.

Resuming Execution after a COBOL STOP RUN Statement

There is a different constraint on resuming after a COBOL STOP RUN statement. When a STOP RUN is issued, Termination Imminent due to Stop (T_I_S) is raised (see "Processing the T_I_S Condition" on page 203 for more information about T_I_S). Therefore, you can respond to a STOP RUN by registering a user-written condition handler to recognize T_I_S.

This condition handler cannot call CEEMRCR with a 0 type_of_move, which means to move the resume cursor to the point in your program just after the STOP RUN statement. This violates the standard definition of a STOP RUN being the last statement to execute in the program in which it is coded. Assuming your program is a subroutine, you could issue a 1 type_of_move to move the resume cursor to the call return point of the stack frame previous to the one of the program that issued the STOP RUN. You could also percolate the condition.
Condition Handling Interactions

Reentering COBOL Programs after Stack Frame Collapse

A stack frame collapse occurs when the condition manager skips over one or more active routines and execution resumes in an earlier routine on the stack. This can occur due to either of the following:

- An explicit GOTO out of block issued from a C or PL/I routine
- Moving the resume cursor using the CEEMRCR callable service and requesting a resume

Language Environment resets any intervening COBOL programs from an active to inactive state, provided they are the following:

- VS COBOL II programs compiled with the CMPR2 compiler option
- VS COBOL II programs compiled with NOCMPR2 that do not use nested programs
- COBOL for OS/390 & VM, COBOL for MVS & VM or COBOL/370 programs compiled with the CMPR2 compiler option or
- COBOL for OS/390 & VM, COBOL for MVS & VM and COBOL/370 programs compiled with NOCMPR2 that do not use the combination of the INITIAL attribute, nested programs, and file processing in the same compilation unit
- Enterprise COBOL for z/OS and OS/390 programs that do not use the combination of the INITIAL attribute, nested programs, and file processing in the same compilation unit

After a stack frame collapse, the routines listed above can be reentered.

Language Environment issues a warning message during stack frame collapse for each intervening COBOL program that does not adhere to the above restrictions. In addition, after the GOTO or resume is performed, any attempt to re-enter these programs is diagnosed as an attempted recursive entry error.

Handling Fixed-Point and Decimal Overflow Conditions

The ON SIZE ERROR phrase continues to be invoked by COBOL to handle fixed-point and decimal overflow conditions, regardless of whether these conditions are enabled by Language Environment.

Fortran Condition Handling Semantics

Fortran language syntax provides limited error handling through the ERR and IOSTAT specifiers that can be coded on Fortran I/O statements, and the STAT specifier that can be coded on Fortran ALLOCATE and DEALLOCATE statements. When ERR, IOSTAT, or STAT are present on a statement, and an error is detected, Fortran semantics take precedence over Language Environment condition handling and control returns immediately to the Fortran program.

Language Environment does not support the use of the Fortran global error option table or extended error handling services.

Arithmetic Program Interruptions from Vector Instructions

When one of the following arithmetic program interruptions occurs during the execution of a vector instruction, the interaction with a condition handler is equivalent to the corresponding exception for a scalar instruction:

- Fixed-point overflow exception
- Exponent-overflow exception
- Exponent-underflow exception
Condition Handling Interactions

- Floating-point divide exception
- Unnormalized-operand exception
- Square-root exception

The unnormalized-operand exception occurs only for vector instructions, but the same considerations apply. Exceptions caused by vector instructions or scalar instructions are comparable in terms of the information available to the condition handler and the possible resume and fix-up and resume actions that the condition handler can request.

Whenever a condition handler is entered because a vector instruction caused one of the arithmetic program interruptions, the information available to that handler represents an exception for only a single element involved in the vector instruction. Both the condition token provided directly to the user condition handler and the qualifying data that it can use are the same as for the corresponding scalar instruction exception. None of this information reflects anything about a vector instruction. Therefore, the condition handler must treat the condition as though it were a scalar exception in which the equivalent scalar instruction is simply one of the successive elementary operations that comprise the vector instruction.

The same resume and fix-up and resume actions for scalar conditions can be requested when they apply to one of the operations that comprise the vector instruction. For example, when the resume with new input value action (result code 60 with a new condition token of CEE0CE) is allowed for the condition and is requested by the user condition handler to provide a new input value for the failing operation, the new input value is used to reexecute the failing vector instruction. This is identical to providing a new input value for a scalar instruction except that a particular element of a vector register is involved. Similarly, when the resume with new output value action (result code 60 with a new condition token of CEE0CF) is allowed for the condition and is requested by the user condition handler to provide a new result for the failing operation, the new result that the user condition handler provides replaces the appropriate element of the vector register. This is identical to providing a new result for a scalar instruction in that the new result replaces whatever the instruction left in its result position; in the vector case, the result position is a particular element of a vector register. For the vector instruction, resumption then occurs by continuing to execute the failing vector instruction but starting with the next element.

Because a vector instruction is semantically equivalent to a loop of elementary operations, more than one arithmetic program interruption can occur for the same vector instruction but for different elements. When this occurs, each exception is presented one at a time as a condition to any condition handlers that are involved.

Restrictions on Using Vector Instructions in User-Written Condition Handlers

When a vector instruction causes a program interruption, no vector instructions can be executed from within any user-written condition handler entered for the condition. In addition, if one of these condition handlers incurs another condition, then subordinate user-written condition handlers that are entered for any nested conditions are also prohibited from executing vector instructions. This restriction is not diagnosed and violation of it causes unpredictable results.
Condition Handling Interactions

PL/I Condition Handling Semantics

VisualAge PL/I condition handling semantics are the same as PL/I except that VisualAge PL/I, like C, ignores any hardware fixed-point overflow exceptions.

When an exception occurs in a PL/I routine, PL/I language semantics for handling the condition prevail. Therefore, the behavior of PL/I condition handling in applications consisting of only PL/I routines is unchanged under Language Environment.

In PL/I, you handle all run-time conditions by writing ON-units. An ON-unit is a procedure that is established in a block when the ON statement for the ON-unit is run. The ON-unit itself runs when the specified condition in the ON statement is raised. The establishment of an ON-unit applies to all dynamically descendent (inherited from calling procedure) blocks of the block that established it; a condition occurring in a called procedure could result in an ON-unit being run in the caller.

This section provides a high-level view of how condition handling works if an exception occurs in a PL/I routine, and only PL/I routines are on the stack. For a more detailed explanation of PL/I condition handling, refer to PL/I for MVS & VM Language Reference. For details about how PL/I condition handling works in an ILC application, see z/OS Language Environment Writing Interlanguage Communication Applications.

PL/I Condition Handling Actions

Refer to Figure 76 throughout the following summary of the steps taken to process a condition when there are only PL/I routines on the stack.

```
<table>
<thead>
<tr>
<th>Step</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Routine 4 SF</td>
</tr>
<tr>
<td>2</td>
<td>Routine 3 SF</td>
</tr>
<tr>
<td>3</td>
<td>Routine 2 SF</td>
</tr>
<tr>
<td>4</td>
<td>Routine 1 SF</td>
</tr>
<tr>
<td>5</td>
<td>3</td>
</tr>
<tr>
<td>6</td>
<td>5</td>
</tr>
<tr>
<td>7</td>
<td>2</td>
</tr>
</tbody>
</table>
```

Figure 76. PL/I Condition Processing

1. Assume a condition such as CONVERSION, which is severity 3, occurs in routine 4.
2. Language Environment moves down the stack towards the earliest stack frame. If a PL/I ON-unit is established for the CONVERSION condition, it is given control.
3. If all stack frames have been visited and no ON CONVERSION unit was found, a message is issued. The condition is promoted to the ERROR condition if it meets any of the qualifications listed in Promoting Conditions to the PL/I ERROR Condition on page 229. Otherwise, the PL/I implicit action occurs. A CONVERSION condition would be promoted to ERROR.
4. The Language Environment condition manager makes another pass of the stack, beginning in Routine 4 where the original condition occurred. If a PL/I ERROR ON-unit is established, it is invoked.
5. If either of the following occurs:
   - An ERROR ON-unit is found, but it does not issue a GOTO out of block
   - No ERROR ON-unit is found

   then the ERROR condition is promoted to T_I_U (Termination Imminent due to an Unhandled Condition). T_I_U maps to the PL/I FINISH condition. (See "Termination Imminent Step" on page 202 for a discussion of T_I_U.)

6. Language Environment makes yet another pass of the stack, beginning in Routine 4 where the original condition occurred. If a PL/I FINISH ON-unit is established, it is invoked.

7. If all stack frames have been visited, and no FINISH ON-unit issued a GOTO out of block, then Language Environment begins thread termination activities in response to the unhandled condition. Since a message was issued for the CONVERSION condition before it was promoted to the ERROR condition, no message is issued at this time.

Promoting Conditions to the PL/I ERROR Condition

PL/I promotes the following conditions to the PL/I ERROR condition:

- Any PL/I condition for which the implicit action is to promote to the ERROR condition. The appropriate ONCODE is used. See PL/I for MVS & VM Language Reference for details.

Mapping Non-PL/I Conditions to PL/I Conditions

Some non-PL/I conditions map directly to PL/I conditions:

- The Language Environment conditions listed in the first column below map directly to the PL/I conditions in the second column.

<table>
<thead>
<tr>
<th>Attention</th>
<th>ATTENTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>Decimal divide</td>
<td>ZERODIVIDE</td>
</tr>
<tr>
<td>Decimal overflow</td>
<td>FIXEDOVERFLOW</td>
</tr>
<tr>
<td>Exponent overflow</td>
<td>OVERFLOW</td>
</tr>
<tr>
<td>Exponent underflow</td>
<td>UNDERFLOW</td>
</tr>
<tr>
<td>Fixed-point divide</td>
<td>ZERODIVIDE</td>
</tr>
<tr>
<td>Fixed-point overflow</td>
<td>FIXEDOVERFLOW</td>
</tr>
<tr>
<td>Floating-point divide</td>
<td>ZERODIVIDE</td>
</tr>
</tbody>
</table>

These Language Environment conditions map directly to the PL/I conditions. They are detected by the hardware and are normally represented by condition tokens with a facility ID of CEE when raised. They are represented by an IBM condition token only when signaled by the PL/I SIGNAL statement.

- The following map directly to ERROR:
  - A Language Environment condition of severity 2, 3, or 4 that does not map to one of the PL/I conditions listed above
    For these conditions, an established ERROR ON-unit is run on the first pass of the stack. In general, the ONCODE is 9999. Some Language Environment conditions that map to ERROR, however, are represented by an ONCODE other than 9999. Examples are some of the conditions raised by the Language Environment math services.
  - Any other condition of severity 2, 3, or 4
    For these conditions, an established ERROR ON-unit is run on the first pass of the stack; the ONCODE is 9999.
Additional PL/I Condition Handling Considerations

Keep the following additional PL/I condition handling considerations in mind:

- Non-PL/I conditions of severity 0 or 1 are not promoted to ERROR.
- Promoting any non-PL/I condition to a PL/I condition is prohibited.
- Raising a PL/I condition using the CEESGL callable service is prohibited.
- Issuing a call to CEEMRCR from within a PL/I ON-unit to move the resume cursor is prohibited. But, you can move the resume cursor by using CEEMRCR from within a Language Environment user-written condition handler.

PL/I Condition Handling Example

Figure 77 on page 231 shows an example of condition handling for PL/I.

Figure 77. PL/I Condition Handling Example (Part 2 of 2)
Language Environment and POSIX Signal Handling Interactions

If you want to run an application that uses POSIX signal handling functions under z/OS UNIX, you need to know how Language Environment condition handling might affect your application. For a detailed discussion of POSIX signal handling functions, see z/OS C/C++ Programming Guide. For details about the Language Environment condition handling model, see Chapter 15, “Language Environment Condition Handling Introduction,” on page 193.

In Language Environment, POSIX signals are distinguished as follows:

Synchronous Signal Handling
If a signal is delivered to the thread that caused the signal to be sent (the incurring thread), and the signal is not blocked, Language Environment’s synchronous signal handling semantics apply and you can use Language Environment condition services to handle the condition as described in "Synchronous POSIX Signal and Language Environment Condition Handling Interactions." Like asynchronous signals, synchronous POSIX signals do not increment the ERRCOUNT error count.

Asynchronous Signal Handling
Asynchronous signals include the following:

- Signals generated because of a kill(), raise(), pthread_kill(), killpg() or sigqueue() (on MVS) in a multithread environment that are delivered to a thread that did not cause the signal to be sent.
- Signals generated because of a kill(), killpg() or sigqueue() (on MVS) from a different POSIX process.
- All signals that were blocked when first sent, and later unblocked.
- Signals generated by an external interrupt not caused by any specific thread. For example, signals can be generated in response to a command typed in at the terminal.
- SIGCHLD, which is sent to a parent process when one of its child processes terminates.
- Signals, such as SIGALRM, generated by the kernel.

Asynchronous signals are handled according to the semantics defined by POSIX. Language Environment condition handling semantics do not apply; for example, the ERRCOUNT run-time option does not increment its error count when an asynchronous signal is sent.

POSIX signal handling can take effect even if no C routine is present on the stack. For example, a COBOL program calls C routine C1. C1 registers a POSIX signal catcher, then C1 returns control to the COBOL program. The registered POSIX signal handler would still be present to handle a POSIX signal even though the stack no longer contains a C stack frame.

Synchronous POSIX Signal and Language Environment Condition Handling Interactions
This section discusses how Language Environment processes most synchronous POSIX signals. (In this section, the term POSIX signal includes both POSIX-defined signals and C-language signals.) With the exception of the POSIX signals listed in "POSIX Signals that Do Not Enter Condition Handling" on page 236, normal Language Environment condition handling steps occur after a specific thread is selected as the target of a possible signal delivery. This applies whether the signal was directed to a specific thread or to a process (or processes).
Synchronous signal handling takes effect for the following signals, unless they are blocked by the signal mask:

- A signal you generate by calling the CEESGL (signal a condition) callable service
- A hardware or software exception caused by a specific thread, which will be delivered to the incurring thread
  These are the exceptions typically caught by ESTAE.
- A kill() to the current process, a raise(), or a sigqueue() if the process has but a single thread or the signal happens to be delivered to the thread that issued the kill(), raise() or sigqueue().
- A pthread_kill() issued by a thread to itself

The signal mask is ignored for a signal caused by a program check.

Language Environment processes POSIX signals by using the three general steps of Language Environment condition handling: enablement, condition, and termination imminent, as described below.

**Enablement Step for Signals under z/OS UNIX**

Figure 78 on page 235 illustrates how z/OS UNIX determines if a signal is enabled, ignored, or blocked. A few POSIX signals do not go through this process. See “POSIX Signals that Do Not Enter Condition Handling” on page 236 for details.

If a signal is ignored or blocked, the signal does not enter Language Environment synchronous condition handling. If a signal is enabled, z/OS UNIX passes it to the Language Environment enablement step (described in “Enablement Step” on page 198). From there, Language Environment either disables the signal, or passes it into the Language Environment condition step.
Condition Step for POSIX Signals under Language Environment

You might find it helpful to read about the Language Environment condition step before reading this section.

1. At each stack frame (or until the condition is handled, or all of your application’s stack frames have been visited), do the following:
   - If a user-written condition handler registered using the CEEHDLR callable service is present on the stack frame, Language Environment gives it a chance to handle the condition.
   - If the signal action was set in a call to signal(), the action requested by the signal handler takes place.
     
     If the signal action was set in a call to sigaction(), sigactionset() or bsd_signal(), the action is ignored until a later step.

2. When all application stack frames have been visited, the incurring stack frame's language defaults are applied.
   C applies its default only if the signal action was set in a call to signal().
   Otherwise, the signal is percolated.

3. If the signal is percolated from the previous step, the following occurs:
   - If the signal is a POSIX signal whose signal action was set in a call to sigaction(), sigactionset() or bsd_signal(), the POSIX action (SIG_DFL or a catcher) is applied.
For any other signal, Language Environment applies its default actions (described in Table 32 on page 202). If the condition that the signal represents is of severity 2 or greater, Language Environment promotes the condition to Termination Imminent due to an Unhandled Condition (T_I_U).

**Termination Imminent Step under z/OS UNIX**

In a POSIX(ON) environment, Language Environment's termination imminent step takes place as described in "Termination Imminent Step" on page 202, with one exception: the behavior of the TERMTHDACT run-time option. If POSIX(ON) is set, TERMTHDACT takes effect only if enclave termination results from a program check or abend, not from signal generating functions such as CEESGL, raise(), kill(), pthread_kill(), killpg() or sigqueue().

**POSIX Signals that Do Not Enter Condition Handling**

Certain POSIX signals do not go through the condition handling steps described above:

- SIGKILL and SIGSTOP cannot be caught or ignored; they always take effect.
- SIGCONT immediately begins all stopped threads in a process if SIG_DFL is set.
- SIGTTIN, SIGTTOU, and SIGSTP immediately stop all threads in a process if SIG_DFL is set.
Chapter 17. Coding a user-written condition handler

This chapter describes how you can code a user-written condition handling routine and provides examples for Language Environment-conforming HLLs.

Understanding the basics

Your user-written condition handler can test for the occurrence of a particular condition by coding a 12-byte condition token or by coding a symbolic feedback code. You can use the Language Environment callable service CEEHDLR to register the condition handler. For information about using CEEHDLR, see "User-written condition handler interface" on page 238.

The USRHDLR run-time option enables you to register a user-written condition handler at stack frame 0 without having to recompile your application to include a call to CEEHDLR. This is particularly useful in supporting Fortran applications because Fortran applications are unable to directly call CEEHDLR.

Nested conditions can be used in your routine as long as the language your routine is written in allows it to be recursively entered. You should design the routine to handle specific conditions rather than designing the routine to handle a wide variety of conditions. You should also code the condition handling routine to respond to the original condition on the first pass of the stack, rather than coding a routine to handle T_I_U on the second pass of the stack. This helps ensure that the handling that you perform addresses the original condition. The more specific the condition is that you design the handler for, the more precise the fix can be.

PL/I Considerations

User condition handlers can now be written in PL/I; that is, you can register a PL/I external procedure as a user-written condition handler using the Language Environment callable service CEEHDLR, and unregister it using CEEHDLU.

Restrictions on PL/I user-written condition handlers are:

- If a user handler is registered in the PL/I main routine, it must be unregistered using CEEHDLU before the main returns via a RETURN statement or by reaching the END statement. One implication is that a user handler registered in the main routine does not gain control for the PL/I FINISH condition raised due to normal termination of the main routine.
- You cannot collapse multiple BEGIN blocks using a RETURN statement when CEEHDLR has been invoked within a nested block.
- The following condition handling pseudovariables and built-in functions are still restricted to PL/I ON-units and are not available in user handlers:
  - DATAFIELD
  - ONCHAR
  - ONCODE
  - ONCOUNT
  - ONFILE
  - ONKEY
  - ONLOC
  - ONSOURCE
- User-written condition handlers are not supported in PL/I multitasking applications.
user-written condition handler may register a user-written condition handler.

A PL/I parameter declared as a structure expects an extra PL/I descriptor; however, Language Environment passes argument lists by reference and has no knowledge of PL/I descriptors. Therefore for the parameter list to be received, declare the parameters with the OPTIONS(BYVALUE) option as shown in Figure 79.

```
PLIHDLR: PROC(ptr1, ptr2, ptr3, ptr4) OPTIONS(BYVALUE);
    DCL (ptr1, ptr2, ptr3, ptr4) POINTER;
    DCL 1 Current_condition BASED(ptr1);
    ;
    DCL Token FIXED BIN(31) BASED(ptr2);
    DCL Result_code FIXED BIN(31) BASED(ptr3);
    DCL 1 New_condition BASED(ptr4);
    ;
```

*Figure 79. Parameter Declarations in a PL/I User-Written Condition Handler*

### Types of conditions you can handle

A user-written condition handler can, in general, intercept and process any condition, regardless of the language of the routine in which the condition occurred. This means that you can code a user-written condition handler to respond to condition tokens with any of the following facility IDs:

- CEE, representing Language Environment and POSIX-defined conditions
- EDC, representing C and C++ conditions
- IGZ, representing COBOL conditions
- FOR, representing Fortran conditions
- IBM, representing PL/I conditions

In general, your user-written condition handler can use any of the Language Environment condition handling services. Specific exceptions follow:

- The ways in which you can resume after an IGZ condition of severity 2 or above are restricted. See “Resuming Execution after an IGZ Condition Occurs” on page 225 for details.
- If an IBM condition of severity 2 or above was raised, then you cannot issue a resume without first moving the resume cursor.
  This restriction does not apply to IBM conditions of severity 0 or 1, or any IBM conditions signaled using the PL/I SIGNAL statement.
- You cannot promote any condition to an IBM condition (one that belongs to PL/I).
  You can promote IBM conditions to conditions with facility IDs of CEE, EDC, FOR, or IGZ.

For more information on coding user-written condition handlers to respond to conditions of different facility IDs, see “Using Symbolic Feedback Codes” on page 289.

### User-written condition handler interface

Use CEEHDLR to register a user-written condition handler. See z/OS Language Environment Programming Reference for more information about CEEHDLR.
User-written condition handlers are automatically unregistered when the stack frame they’re associated with is removed from the stack due to a return, GOTO out of block, or a move of the resume cursor. You can, however, call CEEHDLU to explicitly unregister a user-written condition handler. See z/OS Language Environment Programming Reference for more information about CEEHDLU.

Recursion is allowed if a handler is registered within a handler, and nested conditions are allowed.

It is invalid to promote a condition without returning a new condition token. You cannot promote a condition to a PL/I condition.

### Syntax

```plaintext
condition_handler( c_ctok, token, result_code, new_condition )
```

<table>
<thead>
<tr>
<th>c_ctok (input)</th>
<th>A 12-byte condition token that identifies the current condition being processed. Language Environment uses this parameter to tell your condition handler what condition has occurred.</th>
</tr>
</thead>
<tbody>
<tr>
<td>token (input)</td>
<td>A 4-byte integer that specifies the token you passed into Language Environment when this condition handler was registered by a call to the CEEHDLR callable service.</td>
</tr>
<tr>
<td>result_code (output)</td>
<td>A 4-byte integer that contains instructions about responses the user-written condition handler wants Language Environment to make when processing the condition. The <code>result_code</code> is passed by reference. Valid responses are shown in Table 38.</td>
</tr>
</tbody>
</table>

#### Table 38. Valid Result Codes from User-Written Condition Handlers

<table>
<thead>
<tr>
<th>Response</th>
<th>Result_Code Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>resume</td>
<td>10</td>
<td>Resume at the resume cursor (condition has been handled). Unless the resume cursor has been moved, this response can only be used if the condition being handled specifically allows this form of resumption.</td>
</tr>
<tr>
<td>percolate</td>
<td>20</td>
<td>Percolate to the next condition handler. If a <code>result_code</code> is not explicitly set by a handler, this is the default <code>result_code</code>.</td>
</tr>
<tr>
<td></td>
<td>21</td>
<td>Percolate to the first user-written condition handler for the stack frame that is before the one to which the handle cursor points. This can skip a language-specific condition handler for this stack frame as well as the remaining user-written condition handlers in the queue for this stack frame.</td>
</tr>
</tbody>
</table>
User-Written Condition Handler

<table>
<thead>
<tr>
<th>Response</th>
<th>Result_Code Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>promote</td>
<td>30</td>
<td>Promote to the next condition handler.</td>
</tr>
<tr>
<td></td>
<td>31</td>
<td>Promote to the stack frame before the one to which the handle cursor points. This can skip a language-specific condition handler for this stack frame as well as any remaining user-written condition handler in the queue at this stack frame.</td>
</tr>
<tr>
<td></td>
<td>32</td>
<td>Promote and restart condition handling at the first condition handler of the stack frame of the handle cursor.</td>
</tr>
</tbody>
</table>

**fix-up and resume**

<table>
<thead>
<tr>
<th>Result_Code Value</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>60</td>
<td>Provide the fix-up actions indicated by new_condition and by any qualifying data values that apply to the condition; then resume execution. This response is only allowed if the resume cursor has not been moved and only if the condition being handled allows this response. new_condition must be set by the condition handler to request one of the specific actions for the condition.</td>
</tr>
</tbody>
</table>

If result_code is not explicitly set by the handler, the default response is Value=20, Percolate to the next condition handler.

**new_condition (output)**

A 12-byte condition token that represents either the promoted condition for a promote response (result_code values of 30, 31, and 32) or the requested fix-up actions for a fix-up and resume response (result_code value of 60).

When a result_code of 60, denoting fix-up and resume, is set by the condition handler, new_condition must be set to a condition token that indicates what fix-up action is requested. Many conditions, including mathematical routines, use the condition tokens in Table 39 to resume with corrective action (either resume with new input value or resume with new output value). For some conditions, there may be other condition tokens that can be provided by the condition handler in new_condition to request specific fix-up actions.

Table 39. Designating Requested Fix-up Actions

<table>
<thead>
<tr>
<th>Symbolic Feedback Code (fc)</th>
<th>Severity</th>
<th>Message Number</th>
<th>Fix-up Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE0CE</td>
<td>1</td>
<td>398</td>
<td>Fix-up with new input value. The service that signaled the condition is invoked again with the new argument value provided by the handler as qualifying data.</td>
</tr>
<tr>
<td>CEE0CF</td>
<td>1</td>
<td>399</td>
<td>Fix-up with new output value. The service that signaled the condition returns as its result, the value provided by the handler as qualifying data.</td>
</tr>
</tbody>
</table>

Registering user-written condition handlers using USRHDLR

Use the USRHDLR run-time option to register a user-written condition handler to run at one of the following times (or both):
User-Written Condition Handler

- At stack frame 0 – the condition handler specified as lmname (see syntax below) is invoked after the default HLL condition handler for the main program, but before the HLL condition handler for stack frame 0. The condition percolated or promoted by this user-written condition handler is not passed to any other condition handler.

- The condition handler specified as lmname2 is given control after each condition completes the enablement phase, but before any other registered user condition handler is given control.

Syntax

```
NOUsrhdlr
USrhdlr (lmname1, lmname2)
```

**NOUsrhdlr**

Specifies that no user-written condition handler is registered.

**USrhdlr**

Specifies that a user-written condition handler is registered.

**lmname**

The entry point name or alias name of a load module that contains the user-written condition handler to be registered at stack frame 0.

**lmname2**

The entry point name or alias name of a load module that contains the user-written condition handler to be registered to get control after the enablement phase and before any other condition handler.

The condition handlers registered by the USRHDLR run-time option can return any of the result codes allowed for a condition handler registered with the CEEHDLR callable service.

For more information about using the USRHDLR run-time option, see **z/OS Language Environment Programming Reference**

Nested conditions

A nested condition is one that occurs within a C/C++ signal handler, PL/I ON-unit, or user-written condition handler invoked to handle a condition. When conditions occur during the condition handling process, the handling of the original condition is suspended and further action is taken based on the state of the condition handling.

The DEPTHCONDLMT run-time option indicates whether nested conditions are permitted while your application runs. If you specify DEPTHCONDLMT(1), handling of the initial condition is allowed, but any additional nested condition causes your application to abend. If you specify DEPTHCONDLMT(0), an unlimited number of nested conditions is permitted. If you specify some other integer value for DEPTHCONDLMT, Language Environment allows handling of the initial condition plus additional levels of nested conditions before your application abends (see **z/OS Language Environment Programming Reference** for more information).

If a nested condition is allowed within a user-written condition handler, Language Environment begins handling the most recently raised condition. After the most
User-Written Condition Handler

recently raised condition is properly handled, execution begins at the instruction pointed to by the resume cursor, the instruction following the point where the condition occurred. If a user-written condition handler is registered using CEEHDLR within another user condition handler, nested conditions are handled by the most recently registered condition handler.

If any HLL or user-written condition handler moves the resume cursor closer to the oldest stack frame both conditions are considered handled. The application resumes running at the instruction pointed to by the resume cursor. The resume cursor can be moved using the CEEMRCR callable service, or by language constructs such as GOTO.

Nested conditions in applications containing a COBOL program

You must take special care when dealing with nested conditions in ILC applications. For example, the following scenario can cause your application to abend:

1. A nested condition occurs within a COBOL user-written condition handler (CBLUHDLR). Condition handlers written in COBOL must be compiled with Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM, or COBOL/370.
2. The COBOL user-written condition handler calls another user-written condition handler established using CEEHDLR to handle the nested condition.
3. The user-written condition handler percolates the condition.

In this scenario, the condition can be percolated back to the stack frame where the original condition occurred. Since condition handling actions for the routine where the condition originally occurred include calling CBLUHDLR, CBLUHDLR can be recursively entered. This is not permitted under COBOL/370, and your application abends.

If CBLUHDLR is compiled with Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, or COBOL for MVS & VM; then the recursive call is allowed if RECURSIVE is specified in the PROGRAM-ID. A rule of thumb is to ensure that COBOL user-written condition handlers that call other user-written condition handlers do not regain control or, make sure they are capable of being recursively entered.

Using Language Environment condition handling with nested COBOL programs

If your application contains both nested COBOL programs and calls to Language Environment condition handling services, keep the following in mind:

- Do not call CEEHDLR from a nested COBOL program.
- Do not call CEEMRCR with a 1 type_of_move from a user handler associated with a stack frame that was called by a nested COBOL program. In Figure 80 on page 243 Program A calls nested Program B. Program B calls Program C, which registers a user-written condition handler, UWCHC. UWCHC cannot call CEEMRCR with a 1 type_of_move, which would move the resume cursor back to nested Program B.
Examples with a registered user-written condition handler

This section contains C, C++, COBOL, PL/I, and assembler examples in which user-written condition handlers are registered to respond to specific conditions that might occur in an application.

- In “Signaling and handling a condition in a C/C++ routine” on page 269, C or C++ call CEEHDLR CEEGQDT, and CEEMRCR to respond to a signaled condition.
- In “Handling a divide-by-zero condition in a COBOL program” on page 272, COBOL calls CEEHDLR, CEE3GRN, and CEEMOUT to respond to the significance condition (which was enabled using CEE3SPM).
- In “Handling a program check in an assembler routine” on page 277, assembler calls CEEHDLR to register a condition handler that responds to a program check.

Handling a divide-by-zero condition in C, C++, COBOL, or PL/I

Figure 81 on page 244 and the following examples provide an illustration of how user-written condition handlers can handle conditions such as a divide-by-zero in a C, C++, COBOL, or PL/I application. In Figure 82 on page 245 (for C or C++), Figure 83 on page 248 (for COBOL), and Figure 86 on page 252 (for PL/I), the main routine calls CEEHDLR to register the user-written condition handler (Figure 85 on page 250 for COBOL). The main routine then calls the DIVZERO routine (Figure 84 on page 249 for COBOL), in which a divide-by-zero exception occurs.
Divide-by-zero is enabled as a condition in the following steps:

1. The handle cursor, which first points at DIVZERO’s stack frame, moves down the stack to the USRHDLR condition handler, the first user-written condition handler established to handle conditions for the main routine’s stack frame.

2. For divide-by-zero conditions, USRHDLR issues a call to CEEMRCR (Move Resume Cursor Relative to Handle Cursor) with a 0 type_of_move, meaning move the resume cursor to the call return point of the stack frame associated with the handle cursor. (The call return point is the next instruction after the call to the DIVZERO routine.)

3. Execution resumes in the main routine at this point. A divide-by-zero condition is the only type of program interrupt for which USRHDLR causes a resume.

4. All other program interrupts are percolated to the next condition handler on the stack.

For simplicity, the examples shown below do not include calls to some Language Environment services that could also be useful for handling conditions in your application. For example, you might code in the USRHDLR routine a call to the CEE3GRN callable service in order to get the name of the routine that incurred the condition.

**C or C++ handling a divide-by-zero condition**

Figure 82 on page 245 contains the C/C++ routine that performs the tasks discussed under "Handling a divide-by-zero condition in C, C++, COBOL, or PL/I" on page 243.

User-Written Condition Handler

Figure 87. Usrhdlr Program (PL/I) to Handle Divide-by-Zero Condition
Handling an out-of-storage condition in C, C++, COBOL, or PL/I

You can use the Language Environment condition handling services to resolve an out-of-storage condition in your application. In the user-written condition handler examples that follow, CEEGTST and CEECZST are used to get and reallocate heap storage. CEEMRCR is also used to handle an out-of-storage condition in a user subroutine, and allow the subroutine to be invoked again. For the user code that corresponds to this scenario, see:

- Figure 88 on page 256 and Figure 89 on page 258 for C or C++
- Figure 90 on page 260, Figure 91 on page 263, and Figure 92 on page 265, for COBOL
- Figure 93 on page 266 and Figure 94 on page 268 for PL/I

in which:

1. The out-of-storage condition arises in your subroutine, and Language Environment gives control to the user-written condition handler you have registered through CEEHDLR for the out-of-storage condition.
2. The condition handler detects the out-of-storage condition and calls CEEMRCR to set the resume cursor to resume execution at the return address of your subroutine call.
3. On return from the user condition handler, your main program regains control as if your subroutine has actually run.
4. The main program tests a completion indicator and discovers that the subroutine did not actually complete.
5. Your program then recognizes that it has been invoked with insufficient storage for maximum efficiency, and frees some previously allocated storage.
6. The subroutine is invoked a second time and completes successfully.

See z/OS Language Environment Programming Reference for the syntax of all Language Environment condition handling services.

C/C++ examples using CEEHDLR, CEEGTST, CEECZST, and CEEMRCR

The routine in Figure 88 on page 256 calls CEEHDLR to register a user-written condition handler for the out-of-storage condition, calls CEEGTST to allocate heap storage, and calls CEECZST to alter the size of the heap storage requested.
### User-Written Condition Handler

/*Module/File Name: EDOOSR */

Figure 95. Sample C/C++ Calls to CEEHDLR, CEESGL, CEEQDT, and CEEMRCR (Part 2 of 3)
Handling a divide-by-zero condition in a COBOL program

Figure 96 on page 273 illustrates how a COBOL program can handle a divide-by-zero condition if one should occur. The following occurs:

1. The program enables the divide-by-zero exception. Exceptions can be enabled or disabled by calling the CEE3SPM (Query and Modify Language Environment Hardware Condition Enablement) callable service.
2. The program registers a user-written condition handler that recognizes the divide-by-zero condition.
3. The program then performs a divide-by-zero, which causes the user-written condition handler to get control.
4. The handler calls CEE3GRN (Get Name of Routine that Incurred Condition), to return the name of the routine that the condition occurred in.
5. The handler inserts the routine name and condition token into a user-defined message string, and calls CEEMOUT (Dispatch a Message) to send the message to the Language Environment message file. (The Language Environment message file is a file that you can specify to store messages from a given routine or application, or from all routines that run under Language Environment.)

6. The program uses CEEHDLR to register the user-written condition handler.

```cobol
CBL LIB,QUOTE,NODYNAM
*Module/FileName: IGZTSIGR
******************************************************************************
**   ** IGZTSIGR - Call the following Language Environment services:
**     ** : CEEHDLR - register user condition handler
**     ** : CEE3GRN - get name of routine that incurred the condition.
**     ** : CEEMOUT - output message associated with the condition, including the name of the routine that incurred the condition.
**     **
**     ** 1. Our example registers user condition handler IGZTSIGH.
**     ** 2. Our program then divides by zero, which causes a hardware exception condition.
**     ** 3. IGZTSIGH gets control and prints out a message that includes the name of the routine that incurred the divide-by-zero condition, IGZTSIGR.
**     ** 4. IGZTSIGH requests that Condition management resume execution after the point at which the condition occurred.
**     ** 5. IGZTSIGR terminates normally.

Figure 96. COBOL Example of a Main Program That Calls a Subroutine and Registers a User-Written Condition Handler (Part 4 of 5)
Handling a program check in an assembler routine

Figure 97 on page 278 illustrates how an assembler routine can handle a program check if one should occur. The following occurs:

1. The routine registers a user-written condition handler, LEASMH3D, that responds to a program check by calling CEE3DMP to request a dump.
2. The routine then calls a subroutine, LEASMH2, that generates a program check.
3. The routine gives control to the user-written condition handler.

Note that a condition handler to which an assembler routine gives control does not have to be link-edited into the same load module as the routine; a condition handler can be dynamically loaded and can possibly dynamically load other modules also.

Figure 97. Assembler Example of a Main Routine That Calls a Subroutine and Registers a
User-Written Condition Handler (Part 6 of 6)
Chapter 18. Using Condition Tokens

Language Environment uses the 12-byte condition token data type to perform a variety of communication functions. This chapter describes the format of the condition token and its components, and how you can use the condition token to react to conditions and communicate conditions with other routines.

Understanding the Basics

If you provide an fc parameter in a call to a Language Environment callable service, the service sets fc to a specific value called a condition token and returns it to your application. (See “The Effect of Coding the fc Parameter” on page 286 for more information.)

If you do not specify the fc parameter in a call to a Language Environment service, Language Environment generates a condition token for any nonzero condition and signals it using the CEESGL callable service. Signaling the condition token causes it to be passed to Language Environment condition handling. (See “Effects of Omitting the fc Parameter” on page 287 for more information.)

The condition token is used by the routines of your application to communicate with message services, the condition manager, and other routines within the application. For example, you can use it with Language Environment message services to write a diagnostic message associated with a particular condition to a file. You can also determine if a particular condition has occurred by testing the condition token, or a symbolic representation of it. See “User-written condition handler interface” on page 238 for more information on coding user-written condition handlers. The structure of the condition token is described in “Understanding the Structure of the Condition Token” on page 288, and symbolic feedback codes are discussed in “Using Symbolic Feedback Codes” on page 289.

Language Environment condition tokens contain a 4-byte Instance Specific Information (ISI) token. The ISI token can contain (depending on whether a condition occurred) insert data that further describes the condition and that can be used, for example, to write a specific message to a file. In addition to insert data, the ISI can contain qualifying data (q_data) that user-written condition handlers use to identify and react to a specific condition.

Related Services

Language Environment provides callable services to help you construct and decompose your own condition tokens.

- **CEEDCOD** Breaks down a condition token into its component parts.
- **CEENCOD** Creates a new condition token in your application.

See z/OS Language Environment Programming Reference for a detailed explanation of each field in a condition token and for more information on using CEEDCOD and CEENCOD callable services. See also the message handling services listed in Chapter 19, “Using and Handling Messages,” on page 311.
Using Condition Tokens

The Effect of Coding the fc Parameter

The feedback code is the last parameter of all Language Environment callable services, and the second to last parameter of all Language Environment math services. COBOL/370™ programs must provide the feedback code parameter in each call to a Language Environment callable service; C, C++, Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM, and PL/I routines do not have to do so. (See z/OS Language Environment Programming Reference for information on how to provide the feedback code parameter in each HLL.) When the fc parameter is provided and a condition is raised, the following sequence of events occurs:

1. The callable service in which the condition occurred builds a condition token for the condition. The condition token is a 12-byte representation of a Language Environment condition. Each condition is associated with a single Language Environment run-time message.

2. The callable service places information into the ISI, which might contain the following:
   - A timestamp
   - Information that is inserted into a message associated with the condition
     For example, you can use the CEEBLDTX utility (see “Creating Messages” on page 311) or the CEECMI callable service (see z/OS Language Environment Programming Reference) to generate message inserts. Routines signaling a new condition with a call to CEESGL should first call CEECMI to copy any insert information into the ISI associated with the condition.

3. If the severity of the detected condition is critical (severity = 4), it is raised directly to the condition manager. Language Environment then processes the condition, as described in “Condition Step” on page 200.

4. If the condition severity is not critical (severity less than 4), the condition token is returned to the routine that called the service.

5. When the condition token is returned to your application, you can use the condition token in the following ways:
   - Ignore it and continue processing.
   - Signal it to Language Environment using the CEESGL callable service.
   - Get, format, and dispatch the message for display using the CEEMSG callable service.
   - Store the message in a storage area using the CEEMGET callable service.
   - Use the CEEMOUT callable service to dispatch a user-defined message string to a destination that you specify.
   - Compare the condition token to one that is known to you so that you can react appropriately. You can test the condition token for success, equivalence or equality.
     See z/OS Language Environment Programming Reference for more information about Language Environment callable services.

Testing a Condition Token for Success

To test a condition token for success, it is sufficient to determine if the first 4 bytes are zero; if the first 4 bytes are zero, the remainder of the condition token is zero, indicating that a successful call was made to the service.

The Language Environment condition handling model provides two ways you can check for success using the fc parameter. You can compare the value returned in fc to the symbolic feedback code CEE000, or you can compare it to a 12-byte
condition token containing all zeroes coded in your routine. See “Using Symbolic Feedback Codes” on page 289 for details.

You do not necessarily need to check the feedback code after every invocation of a service or to check for success before proceeding with execution. However, if you want to ensure that your application is invoking callable services successfully, test the feedback code after each call to a service.

Testing Condition Tokens for Equivalence

Two condition tokens are equivalent if they represent the same type of condition, even if not necessarily the same instance of the condition. For example, you could have two occurrences of an out-of-storage condition. Though equivalent conditions, they are not necessarily equal because they occur in different locations in your program.

To determine whether two condition tokens are equivalent, compare the first 8 bytes of each condition token to one another. These bytes are static and do not change depending on the given instance of the condition.

You might want to check for equivalence when writing a message about a type of condition that occurs in your application or when registering a condition handling routine to respond to a given type of condition.

There are two ways to check for equivalent condition tokens:

• You can break down the condition token by coding it as a structure and looking at its individual components, or you can call the CEEDCOD (decompose condition token) service to break down the condition token. See z/OS Language Environment Programming Reference for more information about the CEEDCOD service.

• The easiest way to test for equivalence is to compare the value returned in fc with the symbolic feedback code for the condition you are interested in handling. Symbolic feedback codes represent only the first 8 bytes of a 12-byte condition token. See “Using Symbolic Feedback Codes” on page 289 for details.

Testing Condition Tokens for Equality

To determine whether two condition tokens are equal (that is, the same instance or occurrence of the condition token), you must compare all 12 bytes of each condition token with each other. The last 4 bytes can change from instance to instance of a given condition.

The only way to test condition tokens for equality is to compare the value returned in fc with another condition token that has either been returned from a call to a service, or that you have coded as a 12-byte condition token in your routine. Symbolic feedback codes are used to test for equivalence; they are not useful in testing for equality because they represent only the first 8 bytes of the condition token.

Effects of Omitting the fc Parameter

When a feedback code is not provided, any nonzero condition is raised. Signaled conditions are processed by Language Environment, as described in “Condition Step” on page 200. If the condition remains unhandled at the end of processing, Language Environment takes the Language Environment default action (defined in
Using Condition Tokens

The message delivered is the translation of the condition token into English (or another supported national language).

Understanding the Structure of the Condition Token

Figure 98 illustrates the structure of the condition token, with bit offsets shown above the components:

<table>
<thead>
<tr>
<th>Bit Offset Range</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 - 31</td>
<td>Condition_ID</td>
</tr>
<tr>
<td>32 - 33</td>
<td>Case Number</td>
</tr>
<tr>
<td>34 - 36</td>
<td>Severity Number</td>
</tr>
<tr>
<td>37 - 39</td>
<td>Control Code</td>
</tr>
<tr>
<td>40 - 63</td>
<td>Facility_ID</td>
</tr>
<tr>
<td>64 - 95</td>
<td>ISI</td>
</tr>
</tbody>
</table>

For Case 1 condition tokens, Condition_ID is:

- 0 - 15 Severity Number
- 16 - 31 Message Number

For Case 2 condition tokens, Condition_ID is:

- 0 - 15 Class Code
- 16 - 31 Cause Code

A symbolic feedback code represents the first 8 bytes of a condition token. It contains the Condition_ID, Case Number, Severity Number, Control Code, and Facility_ID, whose bit offsets are indicated.

Figure 98. Language Environment Condition Token

Every condition token contains the components indicated in Figure 98:

**Condition_ID**

A 4-byte identifier that, with the facility ID, describes the condition that the token communicates. The format of Condition_ID depends on whether a Case 1 (service condition) or Case 2 (class/cause code) condition is being represented. Language Environment callable services and most applications can produce Case 1 conditions. Case 2 conditions could be produced by some operating systems and compiler libraries. Language Environment does not produce them directly.

Figure 98 illustrates the format of the Condition_ID for Case 1 and Case 2 conditions.

**Case**

Specifies if the condition token is for a Case 1 or Case 2 condition.

**Severity**

Specifies the severity of the condition represented by the condition token.

**Control**

Specifies if the facility ID has been assigned by IBM.

**Facility ID**

A 3-character alphanumeric string that identifies the product or component of a product that generated the condition; for Language Environment, the facility ID is CEE. Although all Language Environment-conforming HLLs use Language Environment message and condition handling services, the actual run-time messages generated under Language Environment still carry the language identification in the facility ID. The facility ID for PL/I, for example, is IBM.

When paired with a message number, a facility ID uniquely identifies a message in the message source file. The facility ID and message number
Using Condition Tokens

Persist throughout an application. This allows the meaning of the condition and its associated message to be determined at any point in the application after a condition has occurred.

If you are creating a new facility ID to use with your own message source file, follow the guidelines listed under the Facility_ID parameter of CEENCOD in z/OS Language Environment Programming Reference.

If you create a new facility ID to use with a message source file you created using CEEBLDXT (see “Creating Messages” on page 311), be aware that the facility ID must be part of the message source file name. Therefore, you must follow the naming guidelines to ensure the module name does not abend.

ISI

A 4-byte Instance Specific Information token associated with a given instance of the condition. A nonzero ISI token provides instance specific information. The ISI token contains data on message inserts for the message associated with the condition and a q_data_token containing 4 bytes of qualifying data. The ISI token is typically built by Language Environment for system or Language Environment-signaled conditions. It can also be built by an application for conditions signaled using CEESGL. The CEECMI callable service can be used to define the message inserts within the ISI for a condition token. The q_data to be placed in the ISI for a condition token is defined by signaling the condition using CEESGL.

You can extract ISI information inside of CEEHDLR-established condition handlers. The message insert information cannot be retrieved directly; however, the entire formatted message with inserts can be formatted and placed in an application-provided character string using CEEMGET. The q_data_token can be retrieved using CEEGQDT.

Using Symbolic Feedback Codes

Language Environment provides symbolic feedback codes representing the first 8 bytes of a 12-byte condition token. Using Language Environment-provided symbolic feedback codes saves you from having to define an 8-byte condition token in your code whenever you want to check for the occurrence of a condition. Symbolic feedback codes are limited to testing for conditions rather than actual condition instances: no ISI information is tested using symbolic feedback codes because the comparison is only performed against the first 8 bytes of the condition token.

Language Environment provides include files (copy files) that define all Language Environment symbolic feedback codes. See Including Symbolic Feedback Code Files” on page 290 for information about Language Environment symbolic feedback code files.

Locating Symbolic Feedback Codes for Conditions

In Language Environment you can locate symbolic feedback codes in the following ways:

- Look in the first column of the symbolic feedback codes table listed after each of the callable services in z/OS Language Environment Programming Reference. The symbolic feedback code table for the CEEGTST (get heap storage) callable service is shown in Table 40 on page 290.
Using Condition Tokens

Table 40. Symbolic Feedback Codes Associated with CEEGTST

<table>
<thead>
<tr>
<th>Symbolic Feedback Code</th>
<th>Severity</th>
<th>Message Number</th>
<th>Message Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE0P2</td>
<td>4</td>
<td>0802</td>
<td>Heap storage control information was damaged.</td>
</tr>
<tr>
<td>CEE0P3</td>
<td>3</td>
<td>0803</td>
<td>The heap identifier in a get storage request or a d iscard heap request was unrecognized.</td>
</tr>
<tr>
<td>CEE0P8</td>
<td>3</td>
<td>0808</td>
<td>Storage size in a get storage request or a realloca te request was not a positive number.</td>
</tr>
<tr>
<td>CEE0PD</td>
<td>3</td>
<td>0813</td>
<td>Insufficient storage was available to satisfy a get storage request.</td>
</tr>
</tbody>
</table>

To test for the condition raised when you specify an invalid heap ID from which to get storage, you can compare the symbolic feedback code CEE0P3 to the condition token returned either from the service or from the Language Environment condition manager (depending on whether you specified fc in the call to CEEGTST).

• If you want to code a condition handling routine to handle a condition resulting in an error message from your application, see z/OS Language Environment Run-Time Messages, which lists error messages and the symbolic feedback code for conditions.

Including Symbolic Feedback Code Files

Symbolic feedback codes are provided for Language Environment, C or C++, COBOL, Fortran, and PL/I conditions. The symbolic feedback code files are stored in the SCEESAMP sample library. To use symbolic feedback codes, you must include the symbolic feedback code files in your source code. The symbolic feedback code files have file names of the form xxxyyyCT, where:

*xxx*  
Indicates the facility ID of the conditions represented in the file. For example, EDCyyCT contains condition tokens for C- or C++-specific conditions (those with the facility ID of EDC).

*yyy*  
Indicates the facility ID of the language in which the declarations are coded. For example, EDCIBMCT contains PL/I declarations of C condition tokens. *yyy* can be BAL (assembler), EDC (C or C++), FOR (Fortran), IBM (PL/I), or IGZ (COBOL).

*CT*  
Stands for “condition token.”

To use symbolic feedback codes, include the file in your source code using the appropriate language construct, for example:

• In C or C++, to include the file of C or C++ declarations for IGZ (COBOL) condition tokens, specify:
  
  ```c
  #include <igzedcct>
  ```
• In COBOL, define SCEESAMP and use the COPY statement to include the file, as shown below.

Define SCEESAMP in your SYSLIB statement:

```
//SYSLIB DD DSN=Cee.CEE.SCEESAMP,DISP=SHR
```

Specify the following in your COBOL code to include the files containing Language Environment and COBOL condition tokens declared in COBOL:

```
:    COPY CEEIGZCT.
    COPY IGZIGZCT.
```

• In Fortran, to include the Fortran declarations for FOR (Fortran) and CEE (Language Environment) condition tokens, specify the following.

```
INCLUDE (FORFORCT)
INCLUDE (CEEFORCT)
```

• In PL/I, to include the PL/I declarations for IBM (PL/I) and CEE (Language Environment) condition tokens, specify:

```
%INCLUDE IBMIBMCT
%INCLUDE CEEIBMCT
```

Examples Using Symbolic Feedback Codes

The following examples use symbolic feedback codes to test user input and display a message if the input is incorrect.

**C and C++**

In the following example, the symbolic feedback code file CEEEDCCT is included and a call is made to CEEGTST. After the call, a test is made for the condition token representing an invalid heap ID. The fc returned from CEEGTST is tested against the symbolic feedback code CEE0P3 listed in the CEEGTST feedback code table (see z/OS Language Environment Programming Reference). If the heap ID specified is not valid, another call is made to CEEGTST to try again.

_FBCHECK (IBM-supplied) is used to compare only the first 8 bytes of the fc against the symbolic feedback code.
In Figure 100 on page 293, the symbolic feedback code file CEEIGZCT is accessed and a call is made to CEESDEXP (exponential base e). The first 8 bytes of the feedback code returned are tested against the symbolic feedback code CEE1UR to ensure that the input parameter is within the valid range for CEESDEXP. The symbolic feedback code table for CEESDEXP is listed in z/OS Language Environment Programming Reference. A message is displayed if the input parameter is out of range.
It is important that symbolic feedback codes be compared with only the first 8 bytes of the 12-byte condition token. To this end, you must code the COPY statements for the symbolic feedback code declarations in the right place within the condition token declaration.

In [Figure 100], for example, symbolic feedback code CEE1UR is compared to the first 8 bytes of condition token FBC because of the correct placement of the COPY statements.
Using Condition Tokens

It is wrong to place the COPY statements before the declaration of Condition-Token-Value as shown in Figure 101, because the 8-byte symbolic feedback code blank-padded (X'40') to a length of 12 bytes would be compared to the full 12-byte condition token. The comparison would always fail, because the blanks would not match the ISI data in the last 4 bytes of the condition token.

01 FBC
   COPY CEEIGZCT.  ----+ Incorrect
   COPY IGZIGZCT.  ----+ Incorrect
02 Condition-Token-Value
   03 Case-1-Condition-ID.
      04 Severity  PIC S9(4) BINARY.
      04 Msg-No    PIC S9(4) BINARY.
   03 Case-2-Condition-ID
      REDEFINES Case-1-Condition-ID.
      04 Class-Code PIC S9(4) BINARY.
      04 Cause-Code PIC S9(4) BINARY.
   03 Case-Sev-Ctl  PIC X.
   03 Facility-ID  PIC XXX.
   02 I-S-Info     PIC S9(9) BINARY.

Figure 101. Wrong Placement of COBOL COPY Statements for Testing Feedback Code

PL/I

The example in Figure 102 on page 295 includes the symbolic feedback code file CEEIBMCT so that Language Environment feedback codes (with facility ID CEE) will be defined. FBCHECK (IBM-supplied) is called to compare the first 8 bytes of FC with the symbolic feedback code CEE000 to determine if the call to CEEMGET is successful. If it is, the message associated with feedback code CEE001 is printed.

Figure 102. PL/I Example Testing for Symbolic Feedback Code CEE000
Using Condition Tokens

Condition Tokens for C Signals under C and C++

You need the condition token representing an event as input to many Language Environment condition and message handling services. C signals have condition token representations that you can use for this purpose. Table 41 contains condition tokens for C signals seen in C or C++ applications not running in a POSIX environment (for example, C or C++ running POSIX(OFF)). The signals listed in Table 41 have a condition token representation with facility ID of EDC.

q_data Structure for Abends

When Language Environment fields an abend, condition CEE35I (corresponding to message number 3250) is raised. Language Environment provides q_data (qualifying data) for system or user abends as part of the ISI token for condition CEE35I. The q_data can be retrieved using the CEEGQDT callable service from within a CEEHDLR-established condition handler; see "Example Illustrating Retrieval of q_data" on page 298 for an example invocation, and z/OS Language Environment Programming Reference for syntax of the CEEGQDT service. From a Fortran routine, you can use the Fortran-specific callable services and functions described in Language Environment Fortran Run-Time Migration Guide to retrieve the q_data, and you do not need to use the q_data_token. The q_data associated with abends is also listed by message number in z/OS Language Environment Run-Time Messages.

q_data is comprised of a list of addresses pointing to information that can be used by HLL and user-written condition handlers to react to a condition. The q_data structure for an abend is shown in Figure 103 on page 298.

If an abend occurs, Language Environment signals condition CEE35I (corresponding to message number 3250) and builds the q_data structure shown in Figure 103 on page 298.

Using Condition Tokens

**parm count (input)**
A fullword field containing the total number of parameters in the q_data structure, including *parm count*. In this case, the value of *parm count* is a fullword containing the integer 3.

**abend code (input)**
A 4-byte field containing the abend code in the following format:

<table>
<thead>
<tr>
<th>system abend code</th>
<th>user abend code</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>7 8</td>
</tr>
<tr>
<td>19</td>
<td>20</td>
</tr>
<tr>
<td>31</td>
<td></td>
</tr>
</tbody>
</table>

**system abend code**
The 12-bit system completion (abend) code. If these bits are all zero, then the abend is a user abend.

**user abend code**
The 12-bit user completion (abend) code. The abend is a user abend when bits 8 through 19 are all zero.

**reason code (input)**
A 4-byte field containing the reason code accompanying the abend code. If a reason code is not available (as occurs, for example, in a CICS abend), *reason code* has the value zero.

**Usage Notes**

- You can use the CEEGQDT callable service to retrieve the q_data_token; see [z/OS Language Environment Programming Reference](https://www.ibm.com/support/docview.wss?uid=swg25106939) for more information.
- From a Fortran routine, you can retrieve the qualifying data using Fortran-specific callable services and functions, which are described in *Language Environment Fortran Run-Time Migration Guide*.

**Example Illustrating Retrieval of q_data**

Figure 104 on page 299 shows how the abend code can be retrieved from q_data by invoking the CEEGQDT callable service within a CEEHDLR-established condition handler written in COBOL. For an example of a working program that includes the following code, see member IGZTCHDL in library CEE.SCEESAMP.

Figure 104. COBOL Example of Retrieving q_data (Part 2 of 3)
If one of the arithmetic program interruptions shown in Table 43 occurs, and the corresponding condition is signaled, Language Environment builds the q_data structure shown in Figure 105 on page 302.

Table 43. Arithmetic Program Interruptions and Corresponding Conditions

<table>
<thead>
<tr>
<th>Program Interruption</th>
<th>Program Interruption Code</th>
<th>Condition</th>
<th>Message Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed-point overflow exception</td>
<td>08</td>
<td>CEE348</td>
<td>3208</td>
</tr>
<tr>
<td>Fixed-point divide exception</td>
<td>09</td>
<td>CEE349</td>
<td>3209</td>
</tr>
<tr>
<td>Exponent-overflow exception</td>
<td>0C</td>
<td>CEE34C</td>
<td>3212</td>
</tr>
<tr>
<td>Exponent-underflow exception</td>
<td>0D</td>
<td>CEE34D</td>
<td>3213</td>
</tr>
<tr>
<td>Floating-point divide exception</td>
<td>0F</td>
<td>CEE34F</td>
<td>3215</td>
</tr>
<tr>
<td>Unnormalized-operand exception</td>
<td>1E</td>
<td>CEE34U</td>
<td>3230</td>
</tr>
</tbody>
</table>

Notes:
1. The square root exception is also an arithmetic program interruption, but is treated like the condition from the square root mathematical routine.
2. An arithmetic program interruption that occurs on a vector instruction is presented to a user-written condition handler in the same form as though it had occurred on a scalar instruction. A single vector instruction could cause multiple, possibly different, program interruptions to occur, but each interruption is presented individually.
The q_data structure shown in Figure 105 is built by Language Environment for the conditions of exponent overflow, exponent underflow, floating-point divide, fixed-point overflow, fixed-point divide, and unnormalized-operand exceptions. As a result, the q_data structure provides the following information:

q_data_token (input)
The 4-byte address of the address list. This value is returned by the CEEGQDT callable service.

parm_count (input)
A 4-byte binary integer containing the value 6, which is the total number of q_data fields in the q_data structure, including parm_count.

mach_inst_result_desc (input)
The q_data descriptor for mach_inst_result. (See "Format of q_data Descriptors" on page 308 for information on q_data descriptors.)

mach_inst_result (input)
The value left in the machine register (general register, floating-point register, or element of a vector register) by the failing machine instruction. Based on the program interruption, mach_inst_result has one of the following lengths and types (as reflected in the q_data descriptor field mach_inst_result_desc):

<table>
<thead>
<tr>
<th>Program Interruption</th>
<th>Length and Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed-point overflow exception</td>
<td>4- or 8-byte binary integer</td>
</tr>
<tr>
<td>Fixed-point divide exception</td>
<td>8-byte binary integer</td>
</tr>
<tr>
<td>Exponent-overflow exception</td>
<td>4-, 8-, or 16-byte floating-point number</td>
</tr>
<tr>
<td>Exponent-underflow exception</td>
<td>4-, 8-, or 16-byte floating-point number</td>
</tr>
<tr>
<td>Floating-point divide exception</td>
<td>4-, 8-, or 16-byte floating-point number</td>
</tr>
<tr>
<td>Unnormalized-operand exception (occurs only on vector instructions)</td>
<td>4- or 8-byte floating-point number</td>
</tr>
</tbody>
</table>

This is also the result value with which execution is resumed when the user condition handler requests the resume action (result code 10).

fixup_resume_value_desc (input)
The q_data descriptor for fixup_resume_value.
Using Condition Tokens

fixup_resume_value (input/output)
The fix-up value which, for the exceptions other than the unnormalized-operand exception, is the result value with which execution is resumed when the user condition handler requests the fix-up and resume action (result code 60 with a condition token of CEE0CF). fixup_resume_value initially has one of the following values:

• For an exponent-underflow exception, the value 0
• For an unnormalized-operand exception, the value 0
• For one of the other program interruptions, the same value as in mach_inst_result

Based on the program interruption, fixup_resume_value has the following lengths and types (as reflected in the q_data descriptor field fixup_resume_value_desc):

<table>
<thead>
<tr>
<th>Program Interruption</th>
<th>Length and Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fixed-point overflow exception</td>
<td>4- or 8-byte binary integer</td>
</tr>
<tr>
<td>Fixed-point divide exception</td>
<td>8-byte binary integer or two 4-byte binary integers (remainder, quotient)</td>
</tr>
<tr>
<td>Exponent-overflow exception</td>
<td>4-, 8-, or 16-byte floating-point number</td>
</tr>
<tr>
<td>Exponent-underflow exception</td>
<td>4-, 8-, or 16-byte floating-point number</td>
</tr>
<tr>
<td>Floating-point divide exception</td>
<td>4-, 8-, or 16-byte floating-point number</td>
</tr>
<tr>
<td>Unnormalized-operand exception (occurs only on vector instructions)</td>
<td>4- or 8-byte floating-point number</td>
</tr>
</tbody>
</table>

mach_inst_address (input)
The address of the machine instruction causing the program interruption.

Usage Notes

• You can use the CEEQDT callable service to retrieve the q_data_token; see z/OS Language Environment Programming Reference for more information.
• From a Fortran routine, you can retrieve the qualifying data using Fortran-specific callable services and functions, which are described in Language Environment Fortran Run-Time Migration Guide.
• Using the q_data structure, a user condition handler can resume either with:
  – The resume action (result code 10) using the value in mach_inst_result. The effect is the same as though execution had continued without any change to the register contents left by the machine instruction.
  – The fix-up and resume action (result code 60 with a condition token of CEE0CF) for exceptions other than unnormalized-operand. This allows any value to be placed in the result register that the machine instruction used.
• You can use the CEE3SPM callable service to set or reset the exponent-underflow mask bit in the program mask; the bit controls whether a program interruption occurs when exponent-underflow occurs, as follows:
  – When the bit is on, the program interruption occurs and condition CEE34D is signaled.
  – When the bit is off, no program interruption occurs; therefore no condition is signaled.

See z/OS Language Environment Programming Reference for more information on the CEE3SPM callable service.
Using Condition Tokens

q_data Structure for Square-Root Exception

A square-root exception is the program interruption that occurs when a square root instruction is executed with a negative argument. If a square-root exception occurs and the corresponding condition as shown in Table 44 is signaled, Language Environment builds the q_data structure shown in Figure 106 on page 305.

Table 44. Square-Root Exception and Corresponding Condition

<table>
<thead>
<tr>
<th>Program Interruption</th>
<th>Program Interruption Code</th>
<th>Condition</th>
<th>Message Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>Square-root exception</td>
<td>1D</td>
<td>CEE1UQ</td>
<td>2010</td>
</tr>
</tbody>
</table>

For a square-root exception, Language Environment signals the same condition (CEE1UQ) as it does when one of the square root routines detects a negative argument. For this exception, a user-written condition handler can request the same resume and fix-up and resume actions that it can request when the condition is signaled by one of the square root routines.

q_data Structure for Math and Bit-Manipulation Conditions

For conditions that occur in the mathematical or bit manipulation routines, the Language Environment condition manager creates q_data that user condition handlers can use to handle the condition. The q_data structure is shown in Figure 106 on page 305 and is the same for all entry points of the mathematical and bit manipulation routines.
The following information is provided by the `q_data` structure shown in Figure 106:

**q_data_token (input)**

The 4-byte address of the address list. This value is returned by the CEEGQDT callable service.

**parm_count (input)**

A 4-byte binary integer containing the value 10, which is the total number of `q_data` fields in the `q_data` structure, including `parm_count`.

**math_operation (input)**

An 8-byte field containing an abbreviation for the mathematical or bit manipulation operation for which the condition occurred. The field is left-justified and padded with blanks. (See Table 45 on page 307 for a list of the abbreviations.)

**std_resume_value_desc (input)**

The `q_data` descriptor for `std_resume_value`.

**std_resume_value (input)**

A default value used as the result of the mathematical or bit manipulation function when the user condition handler requests the resume action (result code 10). The length and type of this field are dependent on `math_operation` and are reflected in the `q_data` descriptor `std_resume_value_desc`.

---

**Figure 106. q_data Structure for Math and Bit Manipulation Routines**

The diagram shows the structure of the `q_data` with the following fields:

- `q_data_token`
- `parm_count`
- `math_operation`
- `std_resume_value_desc`
- `std_resume_value`
- `parameter_1_desc`
- `parameter_1`
- `parameter_2_desc`
- `parameter_2`
- `fixup_resume_value_desc`
- `fixup_resume_value`
- `parameter_3_desc`
- `parameter_3`
Using Condition Tokens

**parameter_1_desc (input)**
The q_data descriptor for parameter_1.

**parameter_1 (input/output)**
The value of the first parameter provided to the mathematical or bit manipulation routine. The length and type of this field are dependent on math_operation and are reflected in the q_data descriptor parameter_1_desc.

This is the value of the first parameter that is used as input to the routine when the user condition handler requests a resume with new input value (result code 60 with a new condition token of CEE0CE).

**parameter_2_desc (input)**
The q_data descriptor for parameter_2 if the mathematical or bit manipulation routine has two input parameters. (If the routine has only one parameter, the q_data structure has an address slot for this field, but the address is not meaningful and the field must not be referenced.)

**parameter_2 (input/output)**
The value of the second parameter provided to the mathematical or bit manipulation routine if the routine has two input parameters. (If the routine has only one parameter, the q_data structure has an address slot for this field, but the address is not meaningful and the field must not be referenced.) The length and type of the field are dependent on math_operation and are reflected in the q_data descriptor parameter_2_desc.

This is the value of the second parameter that is used as input to the routine when the user condition handler requests a resume with new input value (result code 60 with a new condition token of CEE0CE).

**fixup_resume_value_desc (input)**
The q_data descriptor for fixup_resume_value. (See “Format of q_data Descriptors” on page 308 for more information on q_data descriptors.)

**fixup_resume_value (output)**
The value to be used as the result of the mathematical or bit manipulation function when the user condition handler requests a resume with new output value (result code 60 with a new condition token of CEE0CF). The length and type of this field are dependent on math_operation and are reflected in the q_data descriptor fixup_resume_value_desc.

**parameter_3_desc (input)**
The q_data descriptor for parameter_3 if the mathematical or bit manipulation routine has three input parameters. (If the routine has only one (or two) parameter(s), the q_data structure has an address slot for this field, but the address is not meaningful and the field must not be referenced.)

**parameter_3 (input/output)**
The value of the third parameter provided to the mathematical or bit manipulation routine if the routine has three input parameters. (If the routine has only one (or two) parameter(s), the q_data structure has an address slot for this field, but the address is not meaningful and the field must not be referenced.) The length and type of the field are dependent on math_operation and are reflected in the q_data descriptor parameter_3_desc.

This is the value of the third parameter that is used as input to the routine when the user condition handler requests a resume with new input value (result code 60 with a new condition token of CEE0CE).
### Abbreviations of Math Operations in q_data Structures

Column two shows the abbreviations that can occur in field `math_operation` for the math operations shown in column one.

Usage Notes

- You can use the CEEGQDT callable service to retrieve the q_data_token; see [z/OS Language Environment Programming Reference] for details.
- From a Fortran routine, you can retrieve the qualifying data using Fortran-specific callable services and functions, which are described in Language Environment Fortran Run-Time Migration Guide.
- A user condition handler can request one of three different actions to continue the execution of a failing mathematical or bit manipulation routine:
  - The resume action (result code 10). The value in std_resume_value (either the default value provided to the user condition handler or a modified value provided by the user condition handler) becomes the final result value for the routine.
  - The resume with new input value action (result code 60 with a new condition token of CEE0CE). The values to be used as parameters for invoking the routine again are provided by the user condition handler in parameter_1 and, if applicable, in parameter_2.
  - The resume with new output value action (result code 60 with a new condition token of CEE0CF). The fixup_resume_value value provided by the user condition handler becomes the final result value for the routine.

Format of q_data Descriptors

q_data descriptors contain additional information you need to fix up the parameter or result fields of the math q_data structures, the result field of the program interruption q_data structures, or fields for any conditions whose q_data structures contain q_data descriptors. The descriptors contain information about the length and data type of these fields. The format of the q_data descriptor is illustrated in Figure 107.

```
+0 X'02' data_type_1 X'CE' data_type_2
+4     length
```

*Figure 107. Format of a q_data Descriptor*

The following information is provided by the q_data descriptor shown in Figure 107:

**data_type_1**

A 1-byte binary integer value that, along with data_type_2, indicates the data type. See Table 46 on page 309 for the values and their corresponding data types.

**data_type_2**

A 1-byte binary integer value that, along with data_type_1, indicates the data type. See Table 46 on page 309 for the values and their corresponding data types.

**length**

A 4-byte binary integer value that represents the length of the data.

For each type code that can occur in a q_data descriptor, Table 46 on page 309 shows the corresponding data type.
Table 46. q_data Descriptor Data Types

Using Condition Tokens
Chapter 19. Using and Handling Messages

This chapter describes how you can use the Language Environment message services to create, issue, and handle messages for Language Environment-conforming applications.

Understanding the Basics

The Language Environment message services provide a common method of handling and issuing messages for Language Environment-conforming applications.

When a condition is raised in your application, either Language Environment common routines or language-specific run-time routines can issue messages from the run-time message file. The messages can provide information about the condition and suggest possible solutions to errors.

You can use Language Environment callable services and run-time options to modify message handling, and control the destination of message output. You can also define a message log file to create a record of the messages that Language Environment issues.

Creating Messages

The following sections explain how to create messages to use in your routines. To create a message, you:

1. Create a message source file
2. Assemble the message source file with the CEEBLDTX utility
3. Create a message module table
4. Assign values to message inserts
5. Use messages in code to get message output
Creating a Message Source File

The message source file contains the message text and information associated with each message. Standard tags and format are used for message text and different types of message information. The tags and format of the message source files are used by the CEEBLDXT utility to transform the source file into a loadable TEXT file.

Under TSO/E, if you specify a partially qualified name, TSO/E adds the current prefix (usually userid) as the leftmost qualifier and TEXT as the rightmost qualifier. The message source file should have a fixed record format with a record length of 80.

When creating a message file, make sure your sequential numbering attribute is turned off in the editor so that trailing sequence numbers are not generated. Trailing blanks in columns 1–72 are ignored. At least one message data set (TSO/E) is required for each national language version of your messages.

All tags used to create the source file begin with a colon(:), followed by a keyword and a period(.). All tags must begin in column 1, except where noted. Comments in the message source file must begin with a period asterisk (*.) in the leftmost position of the input line.

**Figure 108** shows an example of a message source file with a facility ID of XMP.

```
:facid.XMP
:msgno.10
:msgsubid.0001
:msgname.EXMPLMSG
:msgclass.I
:msg.This is an example of an insert,
:tab.+1
:ins 1.a simple insert
:msg., within a message.
:xpl.This is a simple example of how to put an insert into a message.
:presp.No programmer response required.
:sysact.No system action is taken.
```

**Figure 108. Example of a Message Source File**

The tags used in message source files are:

**:facid.** The facility ID is required at the beginning of every message file. It is used as the first 3 characters of the message number. All messages within a source file have the same facility ID. For example, all messages issued by Language Environment have a facility ID of CEE. The facility ID is combined with a 4-digit identification number and the message severity code to form the message number. The facility ID can contain any alphanumeric (A–Z, a–z, 0–9) characters.

Omitting the facility ID tag, causes an error during the creation of the loadable message file. Errors are also caused by multiple occurrences of this tag, or by the use of blanks or special characters in the facility ID.

If your C application is running with POSIX(OFF), Language Environment issues messages with a facility ID of EDC for compatibility. For more information, see “Run-Time Messages with POSIX” on page 322.
Using Messages

**Note:** The facility ID is also used as the first 3 characters of the condition token.

:msgno.

**This tag is required.** The message number tag defines the beginning and end of information for a message. All information up to the next :msgno. tag refers to the current message. The message number appears as the 4 digits following the message prefix, and is used to identify the message in a message source file. Multiple messages can use the same message number, but only if a :msgsubid. tag is used within the message.

The message numbers used with the :msgno. tags must be in ascending order. The message numbers can be from 1 to 4 numeric (0–9) characters. Leading zeros will be added if fewer than 4 characters are used.

If your application is running with POSIX(ON), message numbers 5201 through 5209 are used whereas the same messages use message numbers 6000 through 6008 when POSIX(OFF) is in effect. For more information, see "Run-Time Messages with POSIX" on page 322.

:msgsubid.

**This tag is optional.** The message subidentifier tag distinguishes between different messages with the same message number. If every message has a unique message number, the :msgsubid. tag is unnecessary.

The numbers associated with the :msgsubid. tags must be unique and in ascending order within messages that have the same message number. The number associated with the :msgsubid. tag can be from 1 to 4 numeric (0–9) characters. Leading zeros will be added if fewer than 4 digits are used.

:msgname.

The :msgname. tag is used to give a name to a message. This name becomes the symbolic name of the condition token associated with the message, and is placed into the COPY file generated by the CEEBLDTX utility. For example, if EXMPLMSG is used for the :msgname. tag in a message with a facility ID of XMP, the symbolic feedback code for the condition associated with this message is also EXMPLMSG.

If a message name is omitted, the facility ID plus the base-32 equivalent of the message number is used as the symbolic message name. If additionally the :msgsubid. tag is used, the message subidentifier preceded by an underscore is appended to the message name. For example, if :msgno. has a value of 10 and the facility ID is XMP, the symbolic feedback code for the condition associated with a message is XMP00A. If additionally the :msgsubid. tag is used with a value of 0001, the symbolic feedback code is XMP00A_0001.

:msgclass.

**This tag is required.** The :msgclass. (or :msgcl.) tag makes up the final part of the message identification. It requires a case-sensitive character that indicates the severity code of the message. This character corresponds to the level of severity of the condition token associated with the message. If the :msgclass. tag differs from the severity level of the condition token, the severity assigned to the condition token is used. Refer to Table 47 on page 321 for the severity codes, levels of severity, and condition descriptions.

:msg.

The :msg. tag indicates the beginning of partial or complete text of the message to be displayed. The message text can appear in any national language known to Language Environment (including DBCS characters).
Using Messages

For a list of the supported national languages, refer to **Z/OS Language Environment Programming Reference**. The :msg tag can be repeated as often as necessary to construct a message. It is not required if the message consists only of message inserts. If the message text for a message requires more than one line, all lines are left-aligned with the beginning of the first line of message text.

The message text ends with the last nonblank character. There is no fixed space reserved for the message, so there is no requirement to reserve any additional space for message translation.

:hex. The :hex tag indicates the beginning of a hexadecimal character string. If used, it must be within the text of a :msg tag. It is terminated by an :ehex tag. The :hex tag can occur anywhere within the message text.

:ehex. The :ehex tag terminates a string of hexadecimal characters. This tag can occur anywhere within the message text.

:dbc. The :dbc tag defines text of DBCS characters. The string itself cannot contain any SBCS characters, but it must begin with a shift-out character and end with a shift-in character.

:tab.n The :tab tag indicates that the next part of the message will be tabbed over a given number of spaces or tabbed to a given column. If the number is preceded by a plus sign, it indicates the next part of the message will be moved over the specified number of spaces from the current position. Otherwise, the number indicates the column where the next message part will begin. The tab value must be between 1 and 255. If necessary, a new line of output is automatically created to accommodate the tab value. This includes the case where the current position is greater than a specified tab column.

:tbn. The :tbn tag is used to force any text written on a subsequent line to start in the current column until an :etbn tag is found.

:etbn. The :etbn tag turns off the tabs set by a :tbn tag.

:ins n.[text] The :ins tag defines a message insert. The insert is a variable that is assigned a value with the CCECMII callable service. The insert number (n) can be any number between 1 and 9. The text following the period describes the insert. This text is optional, and is included only in a message file when the value assigned to the insert is not known. For example, the text variable name after an insert tag indicates that a variable name is assigned to the insert.

One value can be assigned to each insert used in a message. Insert tags can be moved around, interchanged, or omitted, but the insert values cannot be changed. The order of the :ins n tags, not the insert number, determines the order of the inserts.

:newline. The :newline tag creates a new message line that can be used for multiline messages.

:xpl. *This tag is optional.* The :xpl tag indicates text used to explain the condition. It is not printed as part of the message, but is included if the message SCRIPT file is formatted and printed.

:presp. *This tag is optional.* The :presp tag indicates text that describes the
Using Messages

suggested programmer response. It is not printed as part of the message, but is included if the message SCRIPT file is formatted and printed or displayed online.

**:sysact.**

*This tag is optional.* The **:sysact.** tag indicates text that describes the system action. It is not printed as part of the message, but is included if the message SCRIPT file is formatted and printed or displayed online.

Using the CEEBLDTX Utility

CEEBLDTX is a utility that transforms the message source file into an object format that can then be assembled and loaded. The syntax of the CEEBLDTX invocation is shown below.

**Syntax**

```plaintext
>CCEEBLDTX—\_in_file—\_out_file—\_options
```

**in_file**
The fully qualified data set name of the file containing the message text source. The fully qualified data set name must be enclosed in single quotes if you do not want a TSO/E prefix.

**out_file**
The fully qualified data set name of the resulting ASSEMBLE file containing the text version of the messages. The fully qualified data set name must be enclosed in single quotes if you do not want a TSO/E prefix.

**options**
Can be omitted or be any of the following:

- **C370**(data-set-name)
- **COBOL**(data-set-name)
- **FORTRAN**(data-set-name)
- **PLI**(data-set-name)
- **BAL**(data-set-name)

where **data-set-name** is a fully qualified data set name enclosed in single quotes.

**Usage Note:**
1. Each parameter is positional. Every parameter, except the **options** parameter, is required.

Files Created by CEEBLDTX

The CEEBLDTX utility creates several files. The ASSEMBLE file can be assembled into a loadable text file. When the name of this file is placed in a message module table, the Language Environment message services can dynamically access the file. See "Creating a Message Module Table" on page 318 for more information about creating a message module table.

The COPY or INCLUDE file contains the declarations for the condition tokens associated with each message in the message source file. When this file is included in the source routine, the condition tokens can be used to reference the message. The **:msgname.** tag indicates the symbolic name of the condition token.
Using Messages

To use the CEEBLDTX utility with the sample file shown in Figure 108 on page 312 you would issue:

```
CEEBLDTX example examplasm pli(exmplcop)
```

The in_file is EXAMPLE SCRIPT, the out_file is EXMPLASM ASSEMBLE, and the PL/I options file is EXMPLCOP PLIOPT.

Use High Level Assembler to assemble the ASSEMBLE file into a loadable TEXT file.

**CEEBLDTX Error Messages**

Language Environment issues the following messages for CEEBLDTX errors:

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Message Description</th>
<th>Explanation</th>
<th>Programmer Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>0028</td>
<td>sssssss SCRIPT not found on any accessed disk.</td>
<td>The SCRIPT file with the name sssssss does not exist.</td>
<td>Make sure the name is given correctly and is accessible.</td>
</tr>
<tr>
<td>0040</td>
<td>Error on line nnn in message mmm. Insert number greater than</td>
<td>An insert number greater than the allowable maximum was specified. The current maximum allowable insert number is 9.</td>
<td>Specify an insert number of 9 or less.</td>
</tr>
<tr>
<td>0044</td>
<td>Error on line nnn Duplicate :FACID. tags found with the given script file.</td>
<td>Only one facility ID can be specified in the SCRIPT file.</td>
<td>Specify only one facility ID in the SCRIPT file.</td>
</tr>
<tr>
<td>0048</td>
<td>No :FACID. tag found within the given script file.</td>
<td>A 3-character facility ID must be specified in the SCRIPT file with the :facid. tag.</td>
<td>Specify a 3-character facility ID with the :facid. tag.</td>
</tr>
<tr>
<td>0052</td>
<td>Error on line nnn Message number mmm found out of range mmmm.</td>
<td>A message was found with a number outside the valid range. The current valid range is 0 to 9999.</td>
<td>Correct the invalid message number on the given line of the SCRIPT file.</td>
</tr>
<tr>
<td>0056</td>
<td>Number of hex digits not divisible by 2 on line nnn in message mmm.</td>
<td>Hexadecimal strings must contain an even number of digits.</td>
<td>Specify an even number of digits for the hexadecimal string.</td>
</tr>
<tr>
<td>0060</td>
<td>Invalid hexadecimal digits on line nnn in message mmm.</td>
<td>Valid hexadecimal digits are 0–9 and A–F. Invalid digits were detected.</td>
<td>Specify only digits 0–9 and A–F within a hexadecimal string.</td>
</tr>
<tr>
<td>0064</td>
<td>Number of DBCS bytes not divisible by 2 on line nnn in message mmm.</td>
<td>Doublebyte character strings must contain an even number of bytes.</td>
<td>Specify an even number of bytes for the doublebyte character string.</td>
</tr>
<tr>
<td>0068</td>
<td>PLAS out_file name must be longer than the message facility ID pppp.</td>
<td>The ASSEMBLE file name must be greater than 3 characters.</td>
<td>Specify an ASSEMBLE out_file name of greater than 3 characters.</td>
</tr>
</tbody>
</table>
| 0072 | Message facility ID pppp on line nnn was longer than 4 characters. | Facility ID must be exactly 3 characters long, with no blanks. | Specify a 3-character facility ID.
Using Messages

Return Code=0076  Message class on line nnn was not a valid message class type: IWESCFA.

Explanation: Message class must be one of the valid message classes.

Programmer Response: Specify a valid message class.

Return Code=0080  Tag not recognized on line nnn.

Explanation: A tag that was not recognized was encountered.

Programmer Response: Check the tag for proper spelling and use.

Return Code=0084  The first tag was not a :FACID. tag on line nnn.

Explanation: The first tag of the SCRIPT file must be the facility ID tag.

Programmer Response: Specify the facility ID tag as the first tag in the SCRIPT file.

Return Code=0088  Unexpected tag found on line nnn.

Explanation: A valid tag was found in an unexpected location in the SCRIPT file; it is likely out of order.

Programmer Response: Check the order of the tags in the SCRIPT file.

Return Code=0092  Duplicate tags ttt found on line nnn.

Explanation: Duplicate :msgname., :msgclass., or :msgsubid. tags were found for a single message.

Programmer Response: Remove the extra tag from the message script.

Return Code=0096  No :MSGNO. tags found within the given SCRIPT file.

Explanation: A message file must have at least one message in it, and it must be denoted by a :msgno. tag.

Programmer Response: Specify at least one message in the message file.

Return Code=0100  Insert number was not provided or was less than 1 on line nnn.

Explanation: A positive insert number must be provided for each insert.

Programmer Response: Specify a positive insert number of 9 or less for the insert.

Return Code=0104  Message subid was out of the range mmmm to mmmm on line nnn.

Explanation: A message subid was found with a number outside the valid range. The current valid range is 0 to 9999.

Programmer Response: Correct the invalid message subid on the given line of the SCRIPT file.

Return Code=nnn  Undefined error number nnn issued.

Explanation: An undefined error was encountered.

Programmer Response: Contact your service representative.
Creating a Message Module Table

Creating a Message Module Table

Language Environment locates the user-created messages using a message module table that you code in assembler.

The message module table begins with a header that indicates the number of languages in the table. In Figure 109, for example, only English is used, so the first fullword of the header declares the constant F'1'.

```
TITLE 'UXMMPMSGT'
UXMMPMSGT CSECT
DC F'1' number of languages
DC CL8'ENU' language identifier
DC A(TABLEENU) pointer to first language table
TABLEENU DC F'01' lowest message number in module
DC F'100' highest message number in module
DC CL8'EXMPLASM' message module name
DC F'-1' flags indicating the last...
DC F'-1' 16-byte entry (a dummy entry)...
DC CL8'DUMMY' in the language table
END UXMMPMSGT
```

*Figure 109. Example of a Message Module Table with One Language*

In the message module table shown in Figure 109 on page 319, however, English and Japanese are used, so the first fullword of the header declares the constant F'2'. Following the message module table header are tables for each language.

END UZOGMSGT

Figure 110. Example of a Message Module Table with Two Languages

Each language table has one or more 16-byte entries that indicate the name of a load module and the range of message numbers the module contains. The first fullword of each 16-byte entry contains the lowest message number within the corresponding module; the second fullword contains the highest message number for that module. The last 8 bytes of each 16-byte entry contain the name of the message module to be loaded. For example, in Figure 110 Japanese messages numbered 101–200 are found in module ZOGMSGJ2. Finally, each language table ends with a dummy 16-byte entry whose first two fullwords contain the flag F'-1' indicating the end of the language table.

Use an 8-character format for the title of the message module table: ‘U’ (to indicate that the table contains user-created messages), followed by a 3-character facility ID, followed by ‘MSGT’. For example, the title of the message module table for messages using a facility ID of XMP would be ‘UXMPMSGT’ as shown in Figure 109 on page 318; the title of the message module table for messages having a facility ID of ZOG would be ‘UZOGMSGT’ as shown in Figure 110.

After you create the message module table:
1. Assemble it into a loadable TEXT file using High Level Assembler.
2. Store the message module table in a library where it can be dynamically accessed while your routine is running.

Assigning Values to Message Inserts

After you add message insert tags to the message source file, you can use the Language Environment callable service CEECMI to assign values to the inserts.
Assigning Values to Message Inserts

Values do not need to be assigned to inserts in sequential order. For example, the value of insert 3 can be assigned before the value for insert 1. Before invoking the CEECMI callable service, assign values to the callable service parameters. For more information about CEECMI, see z/OS Language Environment Programming Reference.

Figure 111 shows an example of the use of CEECMI to assign value 1234 to insert 1 for `:msgname.EXMPLMSG` shown in Figure 108 on page 312.

```c
*PROCESS MACRO;
TEST: Proc Options(Main);
/*Module/File Name: IBMMINS */
%
\%INCLUDE CEEIBMAW;
\%INCLUDE CEEIBMCT;
\%INCLUDE SYSLIB(EXMPLCOP);
DECLARE INSERT CHAR(255) VARYING AUTO;
DCL 01 CTOK, /* Feedback token */
  03 MsgSev REAL FIXED BINARY(15,0),
  03 MsgNo REAL FIXED BINARY(15,0),
  03 Flags,
    05 Case BIT(2),
    05 Severity BIT(3),
    05 Control BIT(3),
  03 FacID CHAR(3), /* Facility ID */
  03 ISI /* Instance-Specific Information */
    REAL FIXED BINARY(31,0);
DCL 01 FBCODE, /* Feedback token */
  03 MsgSev REAL FIXED BINARY(15,0),
  03 MsgNo REAL FIXED BINARY(15,0),
  03 Flags,
    05 Case BIT(2),
    05 Severity BIT(3),
    05 Control BIT(3),
  03 FacID CHAR(3), /* Facility ID */
  03 ISI /* Instance-Specific Information */
    REAL FIXED BINARY(31,0);
DECLARE MSGFILE FIXED AUTO;

cток = EXMPLMSG;
insert = '1234';
MSGFILE = 2;
/* Call CEECMI to create a message insert */
CALL CEECMI(ctok, 1, insert, fbcode);
/* Call CEEMSG to issue the message */
CALL CEEMSG(ctok, MSGFILE, fbcode);

END TEST;
```

Figure 111. Example of Assigning Values to Message Inserts

Interpreting Run-Time Messages

Run-time messages are designed to provide information about conditions and possible solutions to errors that occur in your routine. Language Environment common routines and language-specific run-time routines issue run-time messages. All run-time messages in Language Environment are comprised of the following:
A 3-character facility ID used by all messages generated under Language Environment or a particular Language Environment-conforming product. This prefix indicates the Language Environment component that generated the message, and is also the facility ID in the condition token. Language Environment uses the ID of the condition token to write the message associated with the condition to MSGFILE. For more information about the condition token, see Chapter 18, “Using Condition Tokens,” on page 285.

A message number that identifies the message associated with the condition.

A severity level that indicates the severity of the condition that was raised.

The format of every run-time message is **FFFnnnx**

**FFF**

Represents the facility ID. In z/OS Language Environment, the possible facility IDs assigned by IBM are:

- **CEE** Language Environment common library
- **EDC** C language-specific library
- **FOR** Fortran language-specific library
- **IGZ** COBOL language-specific library
- **IBM** PL/I language-specific library

**nnnn**

Represents the message number.

**x** Represents the severity code. This character indicates the level of severity (1, 2, 3, or 4) of the message.

Table 47 lists the severity codes, corresponding severity levels, explanations of the severity codes, and the default actions taken if conditions corresponding to each level of severity are unhandled.

**Table 47. Language Environment Run-Time Message Severity Codes**

<table>
<thead>
<tr>
<th>Severity Code</th>
<th>Level of Severity</th>
<th>Explanation</th>
<th>Default Action If Condition Unhandled</th>
</tr>
</thead>
<tbody>
<tr>
<td>I</td>
<td>0</td>
<td>An informational message (or, if the entire token is zero, no information).</td>
<td>No message issued.</td>
</tr>
<tr>
<td>W</td>
<td>1</td>
<td>A warning message; service completed, probably successfully.</td>
<td>No message issued, except in COBOL. Processing continues for all languages.</td>
</tr>
<tr>
<td>E</td>
<td>2</td>
<td>Error detected, correction attempted, service completed, perhaps successfully.</td>
<td>Issues message and terminates thread.</td>
</tr>
<tr>
<td>S</td>
<td>3</td>
<td>Severe error detected, service incomplete with possible side effects.</td>
<td>Issues message and terminates thread.</td>
</tr>
<tr>
<td>C</td>
<td>4</td>
<td>Critical error detected, service incomplete with condition signaled.</td>
<td>Issues message and terminates thread.</td>
</tr>
</tbody>
</table>

Language Environment messages can appear even though you made no explicit calls to Language Environment services. C, COBOL, and PL/I run-time library routines commonly use the Language Environment services, so you might receive Language Environment messages even when the application routine does not directly call Language Environment services.
Interpreting Run-Time Messages

Some Language Environment conditions have qualifying data associated with the instance specific information (ISI) for the condition. For more information about qualifying data, see "q_data Structure for Abends" on page 297.

Specifying National Language

You can use Language Environment national language support to view run-time messages in mixed- and uppercase U.S. English and in Japanese. You can also use national language support to select the most appropriate language variables for your messages, such as language character set, left-to-right text, single-byte character set (SBCS), and double-byte character set (DBCS).

Language Environment message services support requirements for national language support machine-readable information such as message formatting, message delivery, and normalization (removes the adjacent shift-out, shift-in character in order to make DBCS strings as compatible as possible).

The NATLANG run-time option allows you to set the national language used for messages before you run your routine. The default national language is mixed and uppercase U.S. English. See z/OS Language Environment Programming Reference for more information on the NATLANG run-time option.

The CEE3LNG callable service allows you to set or query the current national language setting while your routine is running. Refer to z/OS Language Environment Programming Reference for more information about CEE3LNG.

Run-Time Messages with POSIX

When your C application is running with POSIX(ON), some messages have changed both facility ID and message number. Messages that had a facility ID of EDC and ranged from message number 6000 through 6008 prior to running with POSIX(ON) now have a facility ID of CEE and use message numbers 5201 through 5209. Messages 5210 through 5233 are new for POSIX(ON) and thus do not have a corresponding POSIX(OFF) message number, except for message 5223, which has a facility ID of EDC and a message number of 6009 while running with POSIX(OFF). When your C application is running with POSIX(OFF), facility ID EDC is still used for message numbers 6000 through 6009.

If your C application is coded to respond to specific facility IDs or specific message numbers for processing, you must specify POSIX(OFF) to receive the facility ID of EDC and message numbers 6000 through 6009.

Table 48 shows the conditions, their condition numbers, and facility IDs.

Handling Message Output

The following sections provide information about directing message output and displaying messages under Language Environment, C, C++, COBOL, Fortran, and PL/I.

For information about handling message output in ILC applications, see [z/OS Language Environment Writing Interlanguage Communication Applications](https://www.ibm.com/support/knowledgecenter/en/SSLTBK_2.2.0/com.ibm.zos/zos.zos Language Environment Writing Interlanguage Communication Applications).
Handling Message Output

Using Language Environment MSGFILE

Run-time messages are directed to a common Language Environment message file. You can use the MSGFILE run-time option to specify the ddname of this file. If a message file ddname is not declared, messages are written to the IBM-supplied default ddname SYSOUT.

The definitions of MSGFILE(SYSOUT) differ, depending on the operating system you use. Table 49 lists the SYSOUT definitions and MSGFILE default attributes for MVS and TSO/E:

<table>
<thead>
<tr>
<th>Operating System</th>
<th>SYSOUT Definition</th>
<th>MSGFILE Default Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVS</td>
<td>SYSOUT=*</td>
<td>LRECL 121, RECFM FBA</td>
</tr>
<tr>
<td></td>
<td>The output is routed to the destination specified in the MSGCLASS option of the JOB card.</td>
<td>If not a terminal, BLKSIZE 121*100; if a terminal, BLKSIZE 121.</td>
</tr>
<tr>
<td>TSO/E</td>
<td>ALLOC DD(SYSOUT) DA(*)</td>
<td>LRECL 121, RECFM FBA, BLKSIZE 121</td>
</tr>
</tbody>
</table>

When you direct run-time messages to an I/O device, the method you should use also depends on the operating system. Table 50 lists methods for directing run-time messages to an I/O device under MVS and TSO/E, and provides references for additional information on this topic.

<table>
<thead>
<tr>
<th>Operating System</th>
<th>Method to Define I/O Device</th>
<th>For additional information, see:</th>
</tr>
</thead>
<tbody>
<tr>
<td>MVS</td>
<td>Specify the ddname of a data set in the JCL.</td>
<td>&quot;Required DD Statements&quot; [72]</td>
</tr>
<tr>
<td>TSO/E</td>
<td>The ddname of the data set that you specify using the ALLOCATE command.</td>
<td>Chapter 6, &quot;Creating and executing programs under TSO/E,&quot; on page 83</td>
</tr>
</tbody>
</table>

Notes:

1. You need to modify existing JCL of pre-Language Environment-conforming applications in order to define new ddnames for MSGFILE.
2. You can specify the same message file across nested enclaves. Language Environment coordinates the use of the same ddname across nested enclaves. If you specify different MSGFILE ddnames in each enclave, Language Environment honors each ddname.
3. Under CICS, the MSGFILE run-time option is ignored. All run-time messages are directed to a transient data queue named CESE rather than to the ddname specified in the MSGFILE option. For more information about message handling and run-time message output under CICS, see "Run-Time Output under CICS" on page 445.

Using MSGFILE under z/OS UNIX

To direct MSGFILE output to a z/OS UNIX file, use the PATH= keyword in the ddname parameter of MSGFILE to specify a ddname that nominates a z/OS UNIX file.
If your application is running in an address space created by using the \texttt{fork()} or \texttt{spawn()} functions or if it is invoked by one of the \texttt{exec} family of functions, the application has access to a DD card only if you dynamically allocate one. If the application can access a DD card, MSGFILE output is directed to that file. If the allocated DD card contains the \texttt{PATH=} keyword, Language Environment directs the MSGFILE output to the hierarchic file system (HFS) file specified.

If your application is running under z/OS UNIX, or under any environment that has file descriptor 2 (FD2) open, MSGFILE output is directed to whatever FD2 points to. Under the shell this is typically your terminal.

If FD2 does not exist but your application is either running in an address space created by the \texttt{fork()} or \texttt{spawn()} functions or invoked by one of the \texttt{exec} family of functions, MSGFILE output is directed to the current working directory; if that directory is the root directory, the output is written to a file in the directory \texttt{/tmp}. The name of the file is the name you specify with the MSGFILE run-time option, with the default of SYSOUT.

The resulting file name has the following format:
\texttt{/path/Fname.Date.Time.Pid}

\textbf{path} The current working directory (unless it is the working directory, in which case it is then \texttt{/tmp}.

\textbf{Fname} The name specified in the FNAME parameter on the call to CEE3DMP (default is CEEDUMP).

\textbf{Date} The date the dump is taken, appearing in the format \texttt{YYYYMMDD} (such as 19940325 for March 25, 1994).

\textbf{Time} The time the dump is taken, appearing in the format \texttt{HHMMSS} (such as 175501 for 05:55:01 PM).

\textbf{Pid} The process ID the application is running in when the dump is taken.

\textbf{Note:} Language Environment cannot direct MSGFILE output to an z/OS UNIX file in a CICS environment.

**Using C or C++ I/O Functions**

C and C++ make a distinction between types of error output, and whether the output is directed to the MSGFILE destination or to one of the standard stream output devices, stderr or stdout.

Run-time messages and perror() messages are directed to the stderr standard stream output device. The default destination for stderr output is the MSGFILE ddname; you can change this default as discussed below.

Message output issued by a call to the printf() function is directed to stdout. For TSO/E, stdout defaults to the terminal. When running batch (MVS, IMS, or TSO/E) or IMS online, stdout attempts by default to open one of several ddnames in the following order of precedence, which is made to open SYSOUT=*= as a data set:

1. SYSPRINT
2. SYSTEM
3. SYSERR
Handling Message Output

You can change the destination of printf() output by redirection. For example, 1>&2 on the command line at routine invocation redirects stdout to the stderr destination.

Table 51 lists the types of C/C++ output, the types of messages associated with them, and the destination of the message output.

Table 51. C and C++ Message Output

<table>
<thead>
<tr>
<th>Type of Output</th>
<th>Type of Message</th>
<th>Produced By</th>
<th>Default Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>MSGFILE output</td>
<td>Language Environment messages (CEExxx)</td>
<td>Language Environment unhandled conditions</td>
<td>MSGFILE ddname</td>
</tr>
<tr>
<td></td>
<td>C library messages</td>
<td>C/C++ unhandled conditions (EDCxxxx)</td>
<td>MSGFILE ddname</td>
</tr>
<tr>
<td>stderr messages</td>
<td>perror() messages (EDCxxx)</td>
<td>Issued by a call to perror()</td>
<td>MSGFILE ddname</td>
</tr>
<tr>
<td></td>
<td>User output sent explicitly to stderr</td>
<td>Issued by a call to fprintf()</td>
<td>MSGFILE ddname</td>
</tr>
<tr>
<td>stdout messages</td>
<td>User output sent explicitly to stdout</td>
<td>Issued by a call to fprintf()</td>
<td>stdout</td>
</tr>
</tbody>
</table>

You can control the destination of stderr and stdout output by using the Language Environment MSGFILE run-time option, the C freopen() function, or by invoking redirection services at run time.

Table 52 lists the possible destinations of redirected stderr and stdout standard stream output.

Table 52. C/C++ Redirected Stream Output

</tr>
</tbody>
</table>

For more information about redirecting standard streams in C or C++, see z/OS C/C++ Programming Guide
Handling Message Output

Using COBOL I/O Statements

Language Environment manages all COBOL output directed to the system-logical output device. This includes output from:
- DISPLAY SYSOUT
- READY TRACE (OS/VS COBOL only)
- EXHIBIT (OS/VS COBOL only)

Note: For OS/VS COBOL programs running under CICS, the DISPLAY, READY TRACE and EXHIBIT statements are not supported.

Non-CICS considerations

For COBOL programs, the DISPLAY statement sends output to MSGFILE(SYSOUT), the default ddname for the Language Environment message file. You can use the COBOL OUTDD compiler option to change the destination of DISPLAY output. The MVS data set to which the run-time messages are written depends on the combination of ddnames specified in the OUTDD compiler option and the MSGFILE run-time option.

If the ddname in OUTDD matches the ddname specified in the MSGFILE run-time option, the output is synchronized with the run-time messages and placed in the MVS data set designated by the MSGFILE run-time option.

If the ddname in OUTDD does not match the ddname specified in the MSGFILE run-time option, the output from the DISPLAY statement is directed to the OUTDD ddname destination.

If the file designated by MSGFILE has not been defined (associated with an I/O device) when the output is delivered, Language Environment dynamically allocates the file with ddname and attributes as shown in Table 49 on page 324.

If the file designated by OUTDD has not been defined when the output is delivered, Language Environment dynamically allocates the file with ddname and attributes as shown in Table 49 on page 324.

For more information about directing COBOL output, refer to Enterprise COBOL for z/OS Programming Guide or COBOL for OS/390 & VM Programming Guide.

CICS considerations

DISPLAY to the system-logical output device is supported under CICS for programs compiled with VS COBOL II, COBOL for MVS & VM, COBOL for OS/390 & VM, and Enterprise COBOL for z/OS and OS/390. The DISPLAY output is written to the Language Environment message file (transient data queue CESE).

Using Fortran I/O Statements

Under Language Environment, Fortran I/O statements formerly written to a Fortran error message unit (either directly or by default) are directed to a Language Environment message file specified by the MSGFILE run-time option. At program initialization, the Fortran error message unit is connected to the file specified by the MSGFILE run-time option.

The following types of output from Fortran programs are directed to the message file:
- Error messages that result from unhandled conditions
- Output produced by a sequential WRITE statement with a unit identifier having a value equal to the Fortran error message unit
Handling Message Output

- Output produced by a sequential WRITE statement with * as the unit identifier when the Fortran error message and the standard print unit are the same
- Output produced by a PRINT statement when the Fortran error message and the standard print unit are the same
- Printed output from the dump services (CDUMP, CPCUMP, DUMP, PDUMP, or SDUMP)

The message file can be either a named or unnamed file. To specify an unnamed file, code the MSGFILE run-time option as follows:

MSGFILE(FTeeF001)

The ee value is a two-character representation of the error message unit number that is specified in the ERRUNIT run-time option; the ee value cannot be any other number.

The default ddname of the Language Environment message file is SYSOUT. The ddname can be changed in a Fortran program by issuing an OPEN statement to connect to the error message unit with a different ddname in the FILE specifier. You can use a CLOSE statement to close the message file currently connected to the Fortran error message unit. In this case, the default message file as specified by the MSGFILE run-time option becomes the current message file. Any subsequent output messages are written to this message file after the CLOSE statement is issued. No subsequent OPEN statement is required.

For example, when the standard print unit is the same as the error message unit (unit 6 in Figure 112), all output from the PRINT statement is directed to the error message unit. When the MSGFILE(ONE) run-time option is in effect, the message file with ddname ONE is connected to the error message unit.

```
PRINT *, 'FILE ONE, RECORD 1'
PRINT *, 'FILE ONE, RECORD 2'
OPEN (6, FILE='TWO')
PRINT *, 'FILE TWO, RECORD 1'
PRINT *, 'FILE TWO, RECORD 2'
CLOSE (6)
PRINT *, 'FILE ONE, NEW RECORD 1'
PRINT *, 'FILE ONE, NEW RECORD 2'
```

Figure 112. Directing Output Messages

Figure 112 shows the first two records being written to the message file with the ddname ONE. The first OPEN statement closes file ONE and connects file TWO to the error message unit; two messages are written to it. The CLOSE statement closes file TWO and makes ONE the current message file. This occurs because the MSGFILE(ONE) run-time option is specified. The next PRINT statement connects file ONE to the error message unit, and two records are written to it. The message file is opened and the error message unit is connected automatically when an output message is issued.

The error message unit is restricted to sequential formatted output operations. Therefore, there are restrictions on the OPEN statement specifiers that can be used for the error message unit. Table 53 on page 329 shows the valid OPEN statement specifiers and specifier values.
Table 53. Allowable OPEN Statement Specifiers

<td>Maximum data length of a message file record.</td>
<td>Any positive value which does not exceed the maximum allowable length of the data in a message file record.</td>
</tr>
</tbody>
</table>

Using PL/I I/O Statements

Run-time messages in PL/I routines are directed to the file specified by the Language Environment MSGFILE run-time option, instead of to the PL/I SYSPRINT STREAM PRINT file.

User-specified output is still directed to the PL/I SYSPRINT STREAM PRINT file by default. To direct this output to the Language Environment MSGFILE file, specify the run-time option MSGFILE(SYSPRINT).

When you use MSGFILE(SYSPRINT):
- Any file constant declaration that includes SYSPRINT STREAM PRINT file attributes is ignored.
- File attributes specified in the SYSPRINT DD card are used.
- If SYSPRINT DD is not present at first file reference, Language Environment dynamically allocates a file with IBM-supplied attributes. See Table 49 on page 324 for MSGFILE file default attributes.
- Any OPENs and CLOSEs to the PL/I SYSPRINT STREAM PRINT file are ignored.
- Synchronization between the types of output (messages and user-specified output) is not provided, so the order of the output is unpredictable.

MSGFILE Considerations When Using PL/I

If MSGFILE(SYSPRINT) is in effect, use SYSPRINT only to direct output to the PL/I SYSPRINT STREAM PRINT file.

Because performance is slower with the MSGFILE(SYSPRINT) option, it is recommended only for debugging purposes. For production applications, direct user-created output to the PL/I SYSPRINT STREAM PRINT file.
Handling Message Output

In a nested enclave environment, you can specify MSGFILE(SYSPRINT) for all enclaves in the application or only for those enclaves containing PUT statements. For batch, multiple enclaves in a Language Environment process can use the PL/I SYSPRINT STREAM PRINT. In this instance, you cannot open the file until it is referenced, and it is closed by Language Environment at process termination.

Under CICS, the MSGFILE run-time option is ignored. Both run-time messages and the SYSPRINT STREAM PRINT file output are directed to the CESE transient data queue. The CESE transient data queue is a CICS thread-level resource. See Chapter 25, “Running Applications under CICS,” on page 433 for more information about the CESE transient data queue.

For more information about directing PL/I output, refer to VisualAge PL/I for OS/390 Programming Guide or PL/I for MVS & VM Programming Guide.

Examples Using Multiple Message Handling Callable Services

The examples in this section show how to use the Language Environment message and condition-handling services to issue a message that relates to a condition token. The same calls are illustrated in C/C++, PL/I, and COBOL.

Each example illustrates how CEEMOUT dispatches an informational message and uses CEENCOD to construct a token for the message. The message area is then initialized, CEEMGET retrieves the message, and CEEDCOD decodes the feedback token from CEEMGET. After all of the message has been retrieved, CEEMOUT issues the message. If any of the services fail, CEEMSG issues an informational error message.
C/C++ Example Calls to CEEMOUT, CEENCOD, CEEMGET,CEEDCOD, and CEEMSG

/*Module/FileName: EDCMSGS */
/**********************************************************
**FUNCTION: CEEMOUT - dispatch a message to message file *

Figure 113. C/C++ Example Illustrating Calls to CEEMOUT, CEENCOD, CEEMGET,CEEDCOD, and CEEMSG (Part 1 of 2)
Construct a token for CEE message 0260.*

```
c_1 = 3;
c_2 = 260;
cond_case = 1;
sev = 3;
control = 1;
memcpy(facid,"CEE",3);
isi = 0;
CEENCOD(&c_1,&c_2,&cond_case,&sev,&control,
  facid,&isi,&token,&fc);
if (_FBCHECK (fc , CEE000 ) != 0 ) {
  printf("CEENCOD failed with message number %d\n",
    fc.tok_msgno);
  exit(2999);
}
```

Initialize the message area.

```
msgindx = 0;
memset(msgarea, '\0',79);
msgarea[80] = '\0';
```

Use CEEMGET until all the message has been retrieved. *
Msgindx will be zero when all the message has been retrieved.*
Call CEEMSG to output error message if CEEMGET fails. *

```
do {
  CEEMGET(&token,msgarea,&msgindx,&fc);
  if (fc.tok_sev > 1) {
    dest = 2;
    CEEMSG(&fc,&dest,NULL);
    exit(2999);
  }
  memcpy(message.string,msgarea,80);
  message.length = 80;
  dest = 2;
  CEEMOUT(&message,&dest,&fc);  // put out the message */
  if ( _FBCHECK (fc , CEE000 ) != 0 ) {
    dest = 2;
    CEEMSG(&fc,&dest,NULL);
    exit(2999);
  }
} while (msgindx != 0);
printf ( "\n**************************************************************************\n");
printf ( "\nCE92MSG C Example is now ended \n"");
printf ( "\n**************************************************************************\n");
```

Chapter 20. Using Date and Time Services

This chapter describes Language Environment date and time services and includes examples showing calls to those services.

Understanding the Basics

Language Environment includes a complete set of callable services that help HLLs perform date and time calculations. You can use these services to read, calculate, and write values representing the date and time. Language Environment offers unique pattern-matching capabilities that let you process almost any date and time format contained in an input record or produced by operating system services.

You can use date and time services to:

• Format date and time values by country code
• Format date and time values using customized formats
• Parse date values and time values
• Convert between Gregorian, Julian, Asian, and Lilian formats
• Calculate days between dates
• Calculate elapsed time to the nearest millisecond
• Get local time and Greenwich Mean Time (GMT) from the system without a supervisor call (SVC) overhead
• Properly handle 2-digit years in the year 2000

All Language Environment date and time services are enabled for national language support, including full DBCS support for the Japanese Emperor era. For more information on national language support, see Chapter 21, “National Language Support,” on page 379.

All Language Environment date and time services are based on the Gregorian calendar, with Lilian limits as described in “Date Limits” on page 340.
Related Services

Callable Services

**CEECLBDY** Converts character date value to the COBOL Integer format. Day one is 01 January 1601 and the value is incremented by one for each subsequent day. This service is similar to CEEDAYS, except that it provides an answer in COBOL Integer format, so that it is compatible with ANSI COBOL intrinsic functions. It should not be used with other Language Environment date or time services.

**CEEDATE** Converts dates in the Lilian format to character values

**CEEDATM** Converts number of seconds to character timestamp

**CEEDAYS** Converts character date values to the Lilian format. Day one is 15 October 1582, and the value is incremented by one for each subsequent day.

**CEEDYWK** Provides day of week calculation

**CEEGMT** Gets current Greenwich Mean Time (date and time)

**CEEGMTO** Gets difference between Greenwich Mean Time and local time

**CEEISEC** Converts binary year, month, day, hour, minute, second, and millisecond to a number representing the number of seconds since 00:00:00 14 October 1582

**CEELOCT** Gets current date and time

**CEEQCEN** Queries the century window

**CEESCEN** Sets the century window

**CEESECI** Converts a number representing the number of seconds since 00:00:00 14 October 1582 to seven separate binary integers representing year, month, day, hour, minute, second, and millisecond

**CEESECS** Converts character timestamps (a date and time) to the number of seconds since 00:00:00 14 October 1582

**CEEUTC** Same as CEEGMT

See [z/OS Language Environment Programming Reference](#) for syntax and examples of these callable services.

---

**Working with Date and Time Services**

Before you can start working with date and time services, you need to know the various formats for specifying date and times and any limits that exist.

**Date Limits**

All Language Environment date and time services are based on the Gregorian calendar, which has certain limits for the date variables. These limits are:

**Starting Lilian Date**

The beginning of the valid Lilian date range (day one) is Friday, 15 October 1582.
1582, the date the Gregorian calendar was adopted. Lilian dates preceding this date are undefined. In the Lilian date range:
- Day zero equals 00:00:00 14 October 1582.
- Day one equals 00:00:00 15 October 1582.

All valid Lilian dates must be after 00:00:00 15 October 1582.

**Starting COBOL Integer Date (ANSI COBOL Intrinsic Functions)**

The beginning of the COBOL Integer date range according to the COBOL standard is 31 December 1600. COBOL Integer dates preceding this date are undefined. In the COBOL Integer date range:
- Day zero equals 00:00:00 31 December 1600.
- Day one equals 00:00:00 01 January 1601.

All valid COBOL Integer dates must be after 00:00:00 01 January 1601.

COBOL has a compiler option, INTDATE, that allows you to get and use Lilian integer dates with COBOL Intrinsic Functions or to use the ANSI starting dates. Use INTDATE(LILIAN) if you want to pass integer dates between programs of different languages and use both Intrinsic Functions and Language Environment callable services to process the integer dates.

**End Lilian Date (End COBOL Integer Date)**

The end of the Lilian date range, as well as the COBOL Integer date range, is set to 31 December 9999. Lilian dates and COBOL Integer dates following this date are undefined.

**Limit of Current Era**

The maximum future date you can express in an era system must be within the first 999 years of the current era. Future dates past year 999 of the current era are undefined.

**Picture Character Terms and Picture Strings**

Picture character terms define the format of date and time fields. A picture string is a template that indicates the format of the input data. For example, the format of the date 06/16/1990 (where 06 is the month, 16 is the day, and 1990 is the year) corresponds to the picture string MM/DD/YYYY. See [z/OS Language Environment Programming Reference](https://www.ibm.com/support/docview.wss?rs=180&context=COM000000&dc=oss&uid=swg27016219) for the Language Environment picture character term and picture string values.

**Notation for Eras**

Calendars based on eras use unique picture strings to identify the eras. The era picture string begins with a less than character (<) and ends with the greater than character (>). The characters between the less than and greater than characters are the era name in DBCS characters.

**Example:**

**Japanese Era**

The six-character string <JJJJ>. An example of specifying the Japanese Meiji era would be to specify X'0E45A645840F' where the X'0E' and X'0F' are the less than character (<) and greater than character (>), respectively. Refer to [z/OS Language Environment Programming Reference](https://www.ibm.com/support/docview.wss?rs=180&context=COM000000&dc=oss&uid=swg27016219) for the Japanese eras used by Language Environment date and time services.
Performing Calculations on Date and Time Values

Language Environment stores a date as a fullword binary integer and a timestamp as a doubleword floating-point value. You can use these formats to perform arithmetic calculations on date and time values, instead of writing special subroutines to do so. Figure 116 is an example of how you can use Language Environment date and time services to convert a date to a different format and perform a simple calculation on the formatted date.

In this example, the number of years of service for an employee is determined using the original date of hire in the format YYMMD DD to make the calculations. The example calculates the total number of years of service for an employee by first calling CEEADAYS to convert the days to Lilian and by then calling CEELOCT (Get Current Local Time) to get the current local time. Then, doh_Lilian is subtracted from today_Lilian (the number of days from the beginning of the Gregorian calendar to the current local time) to calculate the employee’s total number of days of employment. The final calculation divides that number by 365.25 to get the number of service years.

CALL CEEADAYS (date_of_hire, 'YYMMD', doh_lilian, fc)
CALL CEELOCT (today_Lilian, today_seconds, today_Gregorian, fc)
service_days = today_Lilian - doh_lilian
service_years = service_days / 365.25

Figure 116. Performing Calculations on Dates

The valid Lilian date range is 15 October 1582 to 31 December 9999. However, COBOL intrinsic functions uses the COBOL Integer date 01 January 1601 as day one. Language Environment provides the CEECBLDY callable service to allow you to work with the COBOL Integer date format. See z/OS Language Environment Programming Reference for more information on the CEECBLDY service.

Century Window Routines

To process 2-digit years in the year 2000 and beyond, Language Environment employs a sliding scheme called a century window where all 2-digit years lie within a 100-year interval. The default century window for Language Environment is set to start 80 years before the current system date. In the following example, 1993 is the current system date. The century window spans one hundred years from 1913 to 2012 where years 13 through 99 are recognized as 1913-1999 and years 00 through 12 are recognized as 2000-2012.

<table>
<thead>
<tr>
<th>1913</th>
<th>1993</th>
<th>2012</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>System Date</td>
</tr>
</tbody>
</table>

Figure 117. Default Century Window

In 1994, years 14 through 99 are recognized as 1914-1999, and years 00 through 13 are recognized as 2000-2013. By year 2080, all 2-digit years would be recognized as 20xx. In 2081, 00 would be recognized as year 2100.

Some applications might need to set up a different 100-year interval. For example, banks often deal with 30-year bonds, which could be due 01/31/20. You can use the
CEESCEN callable service (see z/OS Language Environment Programming Reference) to change the century window. For example, the following statement sets the default century to the 100-year interval starting 30 years prior to the system date, instead of the Language Environment default of 80 years:

Call CEESCEN(30, fc)

Call CEESCEN(30, fc)

1963 1993 2062

System Date

Figure 118. Using CEESCEN to Change the Century Window

A companion service, CEEQCEN, queries the current century window. A subroutine can, for example, use a different interval for date processing than the parent routine. Before returning, the subroutine resets the interval back to its previous value. For more information about changing the century window, see "Examples Illustrating Calls to CEEQCEN and CEESCEN" on page 344.

National Language Support for Date and Time Services

The NATLANG and COUNTRY run-time options provide national language support for date and time services. The names of the months and days of the week are based on the national language specified in the NATLANG option. Some date and time services also allow the specification of a blank or null picture string, a practice that directs Language Environment to use a date and time format based upon the current value specified in the COUNTRY option. You can locate the default date and time format for any supported country by using the CEEFMDA, CEEFMDT, or CEEFMTM callable services.

Examples Using Date and Time Callable Services

The examples in this section illustrate some of the date conversion and manipulation you can perform by using the Language Environment date and time services together. There are examples for the following services:

- CEEQCEN — Query the century window (see "Examples Illustrating Calls to CEEQCEN and CEESCEN" on page 344)
- CEESCEN — Set the century window (see "Examples Illustrating Calls to CEEQCEN and CEESCEN" on page 344)
- CEESECS — Convert timestamp to seconds (see "Examples Illustrating Calls to CEESCEN" on page 347)
- CEESECS and CEEDATM — Convert timestamp to seconds and build a new timestamp (see "Examples Illustrating Calls to CEESECS and CEEDATM" on page 352)
- CEESECS, CEESECI, CEEISEC, and CEEDATM — Convert timestamp to seconds, convert seconds to date and time components, convert date and time to seconds, and build new timestamp (see "Examples Illustrating Calls to CEESECS, CEESECI, CEEISEC, and CEEDATM" on page 358)
Time and Date Services

- CEEDAYS, CEEDYWK, and CEEDATE — Convert a date to a Lilian date, convert Lilian date to calendar format, and return day of week for the derived Lilian date (see “Examples Illustrating Calls to CEEDAYS, CEEDATE, and CEEDYWK” on page 367).

- CEECBLDY — Converts a date to a COBOL Integer date that is compatible with ANSI COBOL intrinsic functions (see “Calls to CEECBLDY in COBOL” on page 377).

Examples Illustrating Calls to CEEQCEN and CEESCEN

The following sections contain examples to illustrate how to query the current century window and how to set a new window with a new default of 30 years.

Calls to CEEQCEN and CEESCEN in C or C++

#include <string.h>
#include <stdlib.h>
#include <stdio.h>
#include <leaw1.h>
#include <ceedcct.h>

int main (void)
{
  _INT4 oldcen, tempcen;

    strncpy(Time_Stamp.string,TimeStamp,14);
    Time_Stamp.length = 14;

Figure 125. Calls to CEESECS and CEEDATM in C or C++ (Part 1 of 2)
CEESECS takes the user-entered timestamp Time_Stamp and returns a double-precision Lilian seconds tally in Lilian_Seconds.

```c
CEESECS (&Time_Stamp, &picstr, &Lilian_Seconds, &FC);
```

The displacement variable is subtracted from the Lilian seconds tally in Lilian_Seconds.

```c
New_Secs = Lilian_Seconds - displacement * 3600.0;
```

CEEDATM is invoked to get a new timestamp value based on the new Lilian seconds tally in New_Secs.

```c
CEEDATM (&New_Secs, &picstr, New_TimeStamp, &FC);
```

If the _FBCHECK result is zero, the output is printed:

```c
printf("%s is the time %i hours before %s\n", New_Time, displacement, TimeStamp);
```

If the conversion fails, an error message is printed and the CEEMSG function is called.

Examples Illustrating Calls to CEEDEAYS, CEEDATE, and CEEDYWK

The following examples illustrate calls to date and time services to convert a date to a Lilian date (CEEDEAYS). In these examples, a varying number of days are added to the Lilian date, the date is converted back to a character format (CEEDATE), and the day of the week for that Lilian date is returned (CEEDYWK).

```plaintext
CALL CEEISEC (YEAR, MONTH, DAYS, HOURS, MINUTES, SECONDS, 
    MILLSEC, NEW_TIME, FC); 
IF FBCHECK( FC, CEE000) THEN DO; 
    /* CEEDATM is now used to obtain a new timestamp based */ 
    /* on the Lilian seconds tally in variable New_time */ 
    /***************************************************************************/ 
    CALL CEEDATM( NEW_TIME, PICSTR, NEW_TIMESTAMP, FC ); 
    IF FBCHECK( FC, CEE000) THEN DO; 
        PUT SKIP EDIT( 'The time ', DISPLACEMENT, 
            ' months after ', TIMESTAMP, 
            ' is ', NEW_TIMESTAMP ) 
            (A, F(4), (3) A); 
    END; 
    ELSE DO;

END-IF.
GOBACK.

Figure 134. Calls to CEECBLDY in COBOL (Part 2 of 2)

This chapter introduces the national language support services, which you use to set the national language, the country code, currency symbols, and decimal separators. It includes examples showing you how to query the default country code and change it, how to get the default date and time in the new country code, and how to convert the seconds to a timestamp. It also provides guidance for setting national language and country codes, including examples that show how national language services work in conjunction with date and time services.

Understanding the Basics

National language support services allow you to customize Language Environment output (such as messages, RPTOPTS reports, RPTSTG reports, or dumps) for a given country by specifying the following:

- The language in which run-time messages, days of the week, and months are displayed and printed
- A country code that indicates the default date and time format, currency symbol, decimal separator, and thousands separator

Related Options and Services

</tr>
</tbody>
</table>

Most of the tasks you perform with national language support services involve date and time services as well. See Chapter 20, “Using Date and Time Services,” on page 339 for a discussion of callable services for date and time calculations and see z/OS Language Environment Programming Reference for syntax information for all callable services.

Setting the National Language

You can set the national language with the NATLANG run-time option or the CEE3LNG callable service. CEE3LNG is not supported in PL/I multitasking applications. The national language settings affect the error messages, month name, and day of the week name. Message translations are provided for the following languages:

- ENU  Mixed-case U.S. English
- UEN  Uppercase U.S. English
- JPN  Japanese
Setting the Country Code

You can use other national language support services, the COUNTRY run-time option or the CEE3CTY (set default country) callable service, to set the current country code for your application. The country code affects the default formats used to display and print the date and timestamps in the reports generated by the RPTSTG run-time option, RPTOPTS run-time option, and the CEE3DMP (dump) callable service.

Because CEE3LNG and CEE3CTY allow you to maintain multiple national languages and country settings on separate LIFO stacks, you can easily reset the national language or alternate between different country settings. For example, if you want to ensure that a routine in your application outputs the date and time in a Japanese format, use CEE3CTY to query the current default setting and, if necessary, to set it to Japanese with CEE3CTY if some other country code is in effect. For sample user code, see z/OS Language Environment Programming Reference.

C provides locales that map to different combinations of languages, cultural and territorial conventions, and codepages. They establish default formats for the locale-sensitive C-language functions, such as date and time, sorting, and currency symbols. To change the locale, use the setlocale() C-language library function. You can also use Language Environment locale callable services to provide similar functions for internationalized applications (see Chapter 22, “Locale Callable Services,” on page 389). The settings of setlocale() and the COUNTRY run-time option do not affect each other. Likewise, the locale callable services do not affect, nor are they affected by, Language Environment date and time callable services and run-time options. The Language Environment COUNTRY run-time option does, however, affect other Language Environment services; setlocale() affects C functions. You should use both setlocale() and COUNTRY to ensure that the settings for your country are correct.

Language Environment does not currently support certain languages as national languages, so you would not be able to use CEE3LNG to set the national language to an unsupported language. You can, however, change the date and time format so that your English or Japanese banking application, for example, would display the default date and time format for an unsupported language. In general, you must use CEE3CTY to set the conventions for formatting date and time information.

Combining National Language Support and Date and Time Services

To customize your applications for a particular country, use national language support services to query the current country code, which you then can use as input to the Language Environment date and time callable services. For example, you could query the current country code with CEE3CTY and then use the returned value and CEEFMDT to get the default date and time format. When calling the CEEDATM (convert seconds to character timestamp) date and time service, you can use the string returned by CEEFMDT to specify the format of the convert seconds to character timestamp.

Calls to CEE3CTY, CEEFMDT, and CEEDATM in C

This example illustrates how you would query the default country code (CEE3CTY), change it to another country code (CEE3CTY), get the default date and time in the new country code (CEEFMDT), and convert the seconds to a timestamp (CEEDATM).
int main(void) {

    FEEDBACK fc;
    _INT4 function;
    _CHAR4 country, symbol;
    _CHAR80 date_pic;
    _FLOAT8 seconds;
    _VSTRING picstr;
    _CHAR80 timestp;

    #define DE "DE"
    #define BL ""

    printf ("\n***************************************************\n" );
    printf ( "CESCNLS C Example is now in motion\n" );
    printf ( "\n***************************************************\n" );

    /***************************************************************************/
    /* Call CEE3CTY to query the current country setting */
    /***************************************************************************/
    function = 2;
    CEE3CTY(&function,country,&fc);
    if ( (_FBCHECK (fc , CEE000)) != 0 ) {
        printf("CEE3CTY failed with message number \%d\n",fc.tok_msgno);
        exit(2999);
    }

    /***************************************************************************/
    /* Call CEE3CTY to set current country to Germany. */
    /***************************************************************************/
    function = 3;
    CEE3CTY(&function,DE,&fc);
    if ( (_FBCHECK (fc , CEE000)) != 0 ) {
        printf("CEE3CTY failed with message number \%d\n",fc.tok_msgno);
        exit(2999);
    }
}

Figure 135. Querying and Setting the Country Code and Getting the Date and Time Format in C (Part 1 of 2)
Calls to CEE3CTY, CEEFMDT, and CEEDATM in COBOL

The example in Figure 136 on page 383 illustrates how you would query the default country code (CEE3CTY), change it to another country code (CEE3CTY), get the default date and time in the new country code (CEEFMDT), and convert the seconds to a timestamp (CEEDATM).

Chapter 22. Locale Callable Services

This chapter describes how to use the Language Environment locale callable services to internationalize your applications, and includes examples that show how locale callable services work in conjunction with each other. Locale callable services do not affect, nor are they affected by, Language Environment callable services or the COUNTRY or NATLANG run-time options. Language Environment locale callable services are not supported in PL/I multitasking applications.

Language Environment locale support adheres to the standards used by C. For detailed information on these standards, locales, and charmaps, see z/OS C/C++ Programming Guide.

Understanding the Basics

Locale callable services allow you to customize culturally-sensitive output for a given national language, country, and codeset by specifying a locale name.

<table>
<thead>

</tr>
</tbody>
</table>

See z/OS Language Environment Programming Reference for syntax information.

Although C or C++ routines can use the locale callable services, it is recommended that they use the equivalent native C library services instead for portability across platforms. Table 54 shows the Language Environment locale callable services and the equivalent C library routines.

Developing Internationalized Applications

Locale callable services define environment control variables that you can set to establish language-specific information and preferences for an application. Locale callable services also provide a means for establishing global preferences, such as `setlocale()`, locale management services, and locale-dependent interfaces to the application.

Locale callable services allow you to develop applications that can be used in multiple countries, because they can function with specific language and cultural conventions. Such applications are referred to as internationalized applications. These applications have no built-in assumptions with respect to the language, culture, or conventions of their users or the data they process. Instead, language and cultural information is set at run time, a process called localization. Thus, the application processes data provided specifically for a certain locale. In Language Environment, localization occurs at the enclave level.

Examples of Using Locale Callable Services

The following sections demonstrate how to use locale callable services in your applications.

Example Calls to CEEFMON

The following examples illustrate calls to CEEFMON to convert a numeric value to a monetary string using a specified format.

Chapter 23. General Callable Services

This chapter describes the set of Language Environment callable services that provide general services.

Understanding the Basics

The general callable services are a set of callable services that are not directly related to a specific Language Environment function.

Related Services

</table>

See [z/OS Language Environment Programming Reference](#) for syntax information on callable services.

CEE3DMP Callable Service

CEE3DMP generates a dump of Language Environment and the member language libraries. Sections of the dump are selectively included, depending on options specified with the `options` parameter. Output from CEE3DMP is written to the default ddname CCEEDUMP, unless you specify the ddname of another file by using the FNAME option of CEE3DMP. The call to CCEEDUMP does not cause your application to terminate. For an example of a dump and a description of the Language Environment dump service, see [z/OS Language Environment Debugging Guide](#).

CEE3DMP can be called by your application when you want:
- A trace of calls so you can see the order in which applications were called
- A dump of storage and control blocks
- The status of files to determine if a file is open or closed and to see the buffer contents of the file

If your application runs in a non-`fork()` address space, the CCEEDUMP DD statement specifies the name of the dump file. If your application runs in the z/OS UNIX environment, CCEEDUMP DD can contain the PATH= keyword, which specifies the fully qualified HFS path and file name.

Specifying a Target Directory for CCEEDUMPs

If your application runs in an address space for which you issued a `fork()` and the CCEEDUMP DD data set has not been dynamically allocated, the dump is directed according to the following order:
General Callable Services

1. The directory found in environment variable _CEE_DMPTARG
2. Your current working directory, if it is not the root directory (/), and if this directory is writable
3. The directory found in environment variable TMPDIR (which specifies the location of a temporary directory other than /tmp)
4. The /tmp directory

The name of the dump is now CEEDUMP (or the name specified in the FNAME option of CEE3DMP) suffixed with: date.time.process ID.

CEE3USR Callable Service

CEE3USR sets or queries one of two 4-byte fields known as the user area fields. The user area fields are associated with an enclave and are maintained on an enclave basis. A user area might be used by vendor or application programs to store a pointer to a global data area or to keep a recursion counter.

The Language Environment user area fields should not be confused with the PL/I user area. The PL/I user area is a 4-byte field in the PL/I TCA and can only be accessed through assembler language. The PL/I user area continues to be supported for compatibility.

CEEGPID Callable Service

CEEGPID retrieves the Language Environment version ID and the platform ID. The version ID returned by CEEGPID can be tested to determine if you can use new or extended functions that are available in a particular release of Language Environment. For example, POSIX, ENVAR, and CEE3CIB are functions available in Release 3. Before using any of these functions, you can test the Language Environment version to make sure you are running on the release of Language Environment that supports them.

CEERAN0 Callable Service

CEERAN0 generates a sequence of uniform pseudo-random numbers between 0.0 and 1.0 using the multiplicative congruential method with a user-specified seed. The numbers generated are pseudorandom in that the same numbers are generated if the same seed key is used.

CEETEST Callable Service

CEETEST invokes a debug tool, such as the IBM Debug Tool. You can use a debug tool to monitor, trace, and interact with your application while it runs. The invocation is dynamic; the debug tool starts when errors are encountered, so you do not have to run your application under an active debug tool.

The z/OS UNIX dbx Debugging Feature, as well as the IBM Debug Tool, can be used to debug z/OS C/C++ applications that run with POSIX(ON).

Using Some Basic Callable Services

If you plan to use a Language Environment callable service, you must code a call to the service in your source code, then recompile your source under the latest Language Environment-conforming version of the language you are writing in. The standard call to a Language Environment service is different in each language, but does not differ across operating systems.
The following examples illustrate how the CEEFMDT callable service is called in C, C++, PL/I, and COBOL. CEEFMDT sets the default date and time formats for a specified country. In the examples, country is a 2-character fixed-length string representing a Language Environment-defined country code. Picture string (pic_str or PICSTR) is a character string, containing the default date and time for the country, that is returned by CEEFMDT. A feedback code (fc) returned from the service is checked to determine if the service completed correctly.

```c
#include <stdio.h>
#include <string.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main(void) {
    _FEEDBACK fc;
    _CHAR2 country;
    _CHAR80 date_pic;

    /* get the default date and time format for Canada */
    memcpy(country,"CA",2);
    CEEFMDT(country,date_pic,&fc);
    if (!_FBCHECK (fc, CEE000 ) != 0 ) {
        printf("CEEFMDT failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    /* print out the default date and time format */
    printf("%.80s\n",date_pic);
}
```

See **z/OS Language Environment Programming Reference** for detailed instructions on how to call Language Environment services and for more information about the CEEFMDT callable service.
Chapter 24. Math Services

This chapter introduces Language Environment math services and describes the call interface to the math services.

Understanding the Basics

Language Environment math services provide standard math computations and can be called from Language Environment-conforming languages or from Language Environment-conforming assembler routines.

You can invoke Language Environment math services by using the call interface or by using the C, COBOL, Fortran, or PL/I built-in math functions specific to the HLL used in your application. For example, your COBOL program can continue to use the built-in SIN function without having to be recoded to use the CEESxSIN call interface.

Language Environment provides several bit manipulation routines to support existing Fortran functions. The scalar versions of Language Environment bit manipulation routines can be called from programs written in any language. For more information on using bit manipulation routines, see z/OS Language Environment Programming Reference.
### Related Services

#### Math Services
- **CEESxABS**: Absolute value
- **CEESxACS**: Arccosine
- **CEESxASN**: Arcsine
- **CEESxATH**: Hyperbolic arctangent
- **CEESxATN**: Arctangent
- **CEESxAT2**: Arctangent of two arguments
- **CEESxCJG**: Conjugate complex
- **CEESxCOS**: Cosine
- **CEESxCSH**: Hyperbolic cosine
- **CEESxCTN**: Cotangent
- **CEESxDIM**: Positive difference
- **CEESxDVD**: Division

- **CEESxSNH**: Hyperbolic sine
- **CEESxSQT**: Square root
- **CEESxTAN**: Tangent
- **CEESxTNH**: Hyperbolic tangent
- **CEESxXPx**: Exponential (**)

#### Bit Manipulation Routines
- **CEESICLR**: Bit clear
- **CEESISET**: Bit set
- **CEESISHF**: Bit shift
- **CEESITST**: Bit test

See [z/OS Language Environment Programming Reference](#) for syntax and examples of the math services and bit manipulation routines.

---

### Call Interface to Math Services

The syntax for math services has two forms, depending on how many input parameters the routine requires. The first four letters of the math services are always CEES. The fifth character is x, which you replace according to the parameter types listed in "Parameter Types: parm1 Type and parm2 Type" on page 427.
The last three letters indicate the math function performed. In these examples, the function performed is the absolute value (ABS).

### One Parameter

\[\text{CEESxBAS}(\text{parm1}, \text{fc}, \text{result})\]

### Two Parameters

\[\text{CEESxDIM}(\text{parm1}, \text{parm2}, \text{fc}, \text{result})\]

**Parameter Types: parm1 Type and parm2 Type**

The first parameter (parm1) is mandatory. The second parameter (parm2) is used only when you use a math service with two parameters. The x in the fifth space of CEESx must be replaced by a parameter type for input and output. Substitute I, S, D, Q, T, E, or R for x:

- I: 32-bit binary integer
- S: 32-bit single floating-point number
- D: 64-bit double floating-point number
- Q: 128-bit extended floating-point number
- T: 32-bit single floating-complex number (comprised of a 32-bit real part and a 32-bit imaginary part)
- E: 64-bit double floating-complex number (comprised of a 64-bit real part and a 64-bit imaginary part)
- R: 128-bit extended floating-complex number (comprised of a 128-bit real part and a 128-bit imaginary part)

Language Environment math services expect normalized input. Unless otherwise noted, the result has the same parameter type as the input argument. (For functions of complex variables, the image of the input is generally a nonrectangular shape. For this reason, the output range is not provided.) In the routines described in this chapter, the output range for complex-valued functions can be determined from the input range.

C, C++, COBOL, Fortran, and PL/I offer built-in math functions that you can also use under Language Environment. For a description of these functions, see the Reference books for each language in the "Bibliography" on page 635.

Simulation of extended-precision floating-point arithmetic is not supported in PL/I routines under CICS.

**Examples of Calling Math Services**

The following examples illustrate calls to the CEESSLOG math service to calculate the logarithm base e of an argument.
Math Services

Calling CEESSLLOG in C and C++

```c
#include <string.h>
#include <stdio.h>
#include <stdlib.h>
#include <leawi.h>
#include <ceeedcct.h>

int main (void) {
    float int1, intr;

    _FEEDBACK fc;

    int1 = 39;
    CEESSLLOG(&int1,&fc,&intr);
    if ( _FBCHECK ( fc, CEE000 ) != 0 ) {
        printf("CEESSLOG failed with message number %d\n", fc.tok_msgno);
        exit(2999);
    }
    printf("Log base e of \%f is \%f\n",int1,intr);
}
```

Part 4. Using Interfaces to Other Products

This section describes how to use Language Environment with applications that run under CICS, DB2, and IMS.

For a list of products that are compatible with Language Environment, see z/OS Language Environment Run-Time Application Migration Guide or z/OS Language Environment Concepts Guide.
Chapter 25. Running Applications under CICS

Language Environment provides support that, when used in conjunction with facilities provided by the Customer Information Control System (CICS) product, permits you to write applications in high-level languages and run them in a CICS environment. Some of the Language Environment-conforming HLLs might require a later version of CICS. Check the required software list for each language you plan to use.

You can code an application that runs in a CICS environment in Language Environment-conforming C, C++, COBOL, or PL/I. There is no support for any Fortran routines under CICS. Also, Language Environment-conforming assembler main routines are not supported; however, non-main routines are supported under CICS. For more information on running multilanguage applications containing assembler under CICS, see z/OS Language Environment Writing Interlanguage Communication Applications.

This chapter describes special features and considerations that apply to Language Environment-conforming applications running in a CICS environment.

Applications running with POSIX(ON) are only supported in a CICS OTE environment. If you try running an application with POSIX(ON) under non-OTE CICS, you receive a warning message and execution continues.

Applications running with XPLINK(ON) and applications compiled with the XPLINK compiler option are not supported under CICS.

CICS does not support PL/I MTF applications.

Understanding the Basics

Before discussing how to develop and run Language Environment-conforming applications in a CICS environment, it is important to map familiar CICS terminology to the terminology used in the Language Environment program model described in Chapter 13, “Program Management Model,” on page 159.

CICS Region

A CICS region is a fixed-size subdivision of main storage allocated to a job step or system task. For example, a CICS region is established during CICS initialization (start-up job). Initialization of a region creates a common environment for all CICS transactions running in that environment. There are no unique Language Environment services that can be applied at a region level.

CICS Transaction

A CICS transaction is initiated by a single request, usually from a terminal. A CICS transaction is equivalent to a Language Environment process. A Language Environment process consists of one or more enclaves that carry out the needed processing when they are run. When a CICS transaction is initiated, the first Language Environment thread is triggered within the first enclave in the Language Environment process.

For example, the insertion of a bank card into an ATM machine might trigger a Language Environment process (CICS transaction) consisting of one or more enclaves (CICS run units) to read the information on the card. After an ATM
Running Applications under CICS

machine reads a bank card, the validation of the information on the card might be performed by one enclave, processing the user’s personal ID number might be performed by another enclave, processing a user request by another, and dispensing the cash by a final enclave.

CICS Run Unit

A CICS run unit consists of a bound set of one or more load modules that can be loaded by the CICS program loader. Run units are equivalent to Language Environment enclaves. Any link-edited load module is an enclave in CICS; each enclave has its own entry in the CICS PPT. Under CICS, it is possible for a single enclave to have multiple load modules link-edited with separate entries in the PPT. Each enclave has its own heap storage and other Language Environment resources associated with it.

An enclave is invoked when a Language Environment process (CICS transaction) is triggered or when it is passed control from another enclave using the EXEC CICS LINK or EXEC CICS XCTL commands. For details on using EXEC CICS LINK or EXEC CICS XCTL commands, see Creating child enclaves with EXEC CICS LINK or EXEC CICS XCTL on page 556.

Running Language Environment Applications under CICS

The following steps describe basic application execution under CICS:

1. An event, generally the receipt of an input message containing a transaction ID code, triggers a Language Environment process (CICS transaction).
2. CICS looks up the transaction ID code in the program control table (PCT) and gets the name of the enclave (or the first enclave) to execute the process.
3. CICS defines the process (transaction) as a work item that is dispatched by the CICS task dispatcher.
4. After the process is defined, CICS looks up the identity of the enclave required to perform the task in the processing program table (PPT). The PPT contains information about the enclave such as its language, whether it is in storage, and if in storage, its use count and entry point address.
5. CICS calls the Language Environment-CICS run-time level interface to initialize the process-related portions of the run-time environment.
6. If the enclave does not perform all the processing associated with the process, the enclave might pass control to another enclave through a language call or through the EXEC CICS LINK or EXEC CICS XCTL commands.
7. When the process is complete, CICS calls the Language Environment-CICS run-time level interface to terminate the process-related portions of the run-time environment.

Developing an Application under CICS

Certain coding restrictions apply when you develop an application to run under CICS. Examples are:

- Input/output restrictions — CICS provides its own I/O facilities using various EXEC CICS commands.
- Multitasking — CICS has its own multitasking capability.

After you code your application, you must run it through a CICS translator. The translator accepts as input an application containing EXEC CICS commands and produces as output an equivalent application in which each CICS command has
been translated into the language of the source. The CICS translator runs in a separate job step. The job step sequence for preparing and running an application under CICS is:

1. Code
2. Translate
3. Compile
4. Prelink
5. Link-Edit
6. Run

C coding restrictions are described in "z/OS C/C++ Programming Guide". COBOL restrictions are discussed in "Enterprise COBOL for z/OS Programming Guide" and in "COBOL for OS/390 & VM Programming Guide". Examples of PL/I coding restrictions under CICS are discussed in "PL/I Coding Considerations under CICS" below.

For more information on developing an application under CICS, see "CICS Application Programming Guide"

**PL/I Coding Considerations under CICS**

CICS imposes some coding restrictions on PL/I routines:

- MTF routines — CICS does not support PL/I MTF applications.
- Built-in subroutines — There are some restrictions on the use of PL/I’s built-in subroutines:
  - You cannot use the PLISRTx interfaces, PLICKPT or PLICANC.
  - You can use PLIRETC and PLIRETV to communicate between user-written routines that are link-edited together, but not to communicate with CICS. See "Managing return codes in Language Environment" on page 151 for details.
- Debugging facilities — Support has been added to allow the CICS transaction to be debugged using the Debug Tool. To prepare your program to use the Debug Tool, you must compile with the TEST option. For more information on debugging under Language Environment, see "z/OS Language Environment Debugging Guide". For more information on debugging CICS transactions using the Debug tool, see "Debug Tool Users Guide".
- Language I/O facilities — You can use only a subset of PL/I I/O facilities under CICS.
  - OPEN/CLOSE can be used, but only for the SYSPRINT file
  - You can use stream output only to the SYSPRINT file. For performance reasons, you should use stream output under CICS only when debugging your applications.

Those PL/I I/O facilities that you cannot use under CICS are:

- Record I/O statements
- Stream input
- DISPLAY statement
- DELAY statement
- STOP statement
- WAIT statement
- PL/I I/O-related conditions such as RECORD, TRANSMIT, ENDFILE, and KEY are not raised under CICS, because I/O is not performed using PL/I files (except SYSPRINT) and I/O statements. CICS file-handling facilities are used instead. If CICS detects an I/O condition during the processing of your commands, CICS deals with the condition in the way defined in the CICS manuals.
Running Applications under CICS

Link-Edit Considerations under CICS

You can link-edit Language Environment-conforming applications that are to be executed under CICS as if they were MVS batch applications. If your C, C++, COBOL, or PL/I application uses EXEC CICS commands, however, you must also link-edit the EXEC CICS interface stub, DFHELII, with your application. To be link-edited with your application, DFHELII must be available in the link-edit SYSLIB concatenation; DFHELII is in the SDFLOAD library. For more information, see "CICS System Definition Guide".

C and C++ Considerations

C and C++ applications must be link-edited AMODE(31), RMODE(ANY), as shown in "C/C++ AMODE/RMODE Considerations" on page 14.

COBOL Considerations

DFHELII is compatible with the DFHECI stub provided for COBOL programs. Although DFHECI is still supported under Language Environment, DFHELII offers some advantages. Whereas the old COBOL stub had to be link-edited at the top of your application, DFHELII can be linked anywhere in the application. You also have the capability of linking ILC applications with a single stub rather than with multiple stubs.

PL/I Considerations

CEESTART is the only entry point for VisualAge PL/I and PL/I for MVS & VM applications. To relink OS PL/I object modules with z/OS Language Environment, you must use the following linkage-editor statements:

```
INCLUDE SYSLIB(CEESTART)
INCLUDE SYSLIB(CEESG010)
INCLUDE SYSLIB(DFHELII)
REPLACE PLISTART
CHANGE PLIMAIN(CEEMAIN)
INCLUDE objlib(objmod)
```

where:

- `objlib` Represents the PDS that contains the object code
- `objmod` Represents the name of the object module
- `loadmod(R)` Represents the name of the resultant load module

The INCLUDE statement for the object module must occur immediately after the CHANGE statement. The object module of the main procedure must be included before the object modules of subroutines, if any; this was not required for OS PL/I applications.

CICS Processing Program Table (PPT) Considerations

All of the routines that you dynamically call or fetch in your application must be defined in the CICS PPT. Previously, you had the following choices for the LANG option of the PPT entry: ASM, C, COBOL, and PLI.

Now, however, you can specify 'LE' (Language Environment) as the language of any Language Environment-conforming routine. This can save you time when you replace a routine with one written in a different language, because you do not need to redefine the routine in the PPT. C++ programs and all VisualAge PL/I CICS programs must specify LANG(LE) for the PPT entry.
Specifying Run-Time Options under CICS

Under CICS, you cannot pass run-time options as parameters when the application is invoked. However, you can specify run-time options for your application using one of the following methods:

- As default options established in CEECOPT during the installation of Language Environment (for more information about CEECOPT, see page 117).
- As CICS and IMS region-wide default options established at any time in CEEROPT (for more information about CEEROPT, see page 117).
- In C++ programs, as static ILC to C modules that have a #pragma runopts statement.
- As application defaults established in CEEUOPT (see page 117 and CEEXOPT Invocation Syntax” on page 124 for details).
- In the user exit (see “CEEBXITA Assembler User Exit Interface” on page 463 for details on how to do this).
- In C applications, as options specified using #pragma runopts (see page 119 for the proper syntax).
- In PL/I applications, as default options established in CEEUOPT using the PLIXOPT string (for more information, see Chapter 9, “Using Run-Time Options,” on page 117).

Some run-time options have different defaults and exhibit slightly different behavior while executing under CICS. The options are listed in Table 55

### Accessing DLI Databases from CICS

Various user interfaces to DLI databases on IMS are available under CICS. See Appendix B, “EXEC DLI and CALL IMS Interfaces,” on page 589 for details.

### Using Callable Services under CICS

All Language Environment callable services are available to applications executing as CICS transactions. However, the CEEMOUT (dispatch a message) and CEE3DMP (generate dump) services differ, in that the messages and dumps are sent to a transient data queue called CESE rather than to the ddbname specified in the MSGFILE run-time option. See z/OS Language Environment Programming Reference for descriptions of these services.

See z/OS Language Environment Writing Interlanguage Communication Applications for ILC examples that make a call to CEEMOUT.

### OS/VS COBOL Compatibility Considerations under CICS

Language Environment provides a set of compatibility library routines that permit you to run OS/VS COBOL applications under CICS in compatibility mode. When you run an OS/VS COBOL application on CICS, the environment that is established for a run unit by the compatibility library routines supports only OS/VS COBOL. This
Running Applications under CICS

compatibility library does not contain many of the services normally offered under Language Environment. Language Environment run-time options and callable services, for example, are not supported.

Using Math Services in PL/I under CICS

Simulation of extended-precision floating-point arithmetic is not supported in PL/I routines under CICS.

PL/I saves and restores floating-point registers where necessary. PLIDUMP can print these registers (for more information about PLIDUMP, see z/OS Language Environment Debugging Guide).

Floating-point overflow and underflow can be handled in OVERFLOW and UNDERFLOW ON-units. The program mask is set appropriately for the levels of CICS and PL/I used.

Coding Program Termination in PL/I under CICS

You can terminate a PL/I routine running under CICS by using PL/I constructs or CICS statements such as EXEC CICS RETURN, EXEC CICS SEND PAGE RELEASE, EXEC CICS XCTL, or EXEC CICS ABEND. When the routine terminates, the following occurs:

1. If you requested a storage report using the RPTSTG run-time option, the report is written to the CESE transient data queue (described in “Run-Time Output under CICS” on page 445).
2. If CESE is still open, it is closed.
3. All storage acquired by PL/I is freed before control returns to CICS, except for the stack.

Storage Management under CICS

Applications can allocate and free storage explicitly through language facilities, CICS facilities (EXEC CICS GETMAIN and FREEMAIN commands, for more information, see CICS Application Programming Guide), or the Language Environment storage management callable services.

If you do not explicitly free storage that was allocated through language facilities or Language Environment callable services, the storage is freed at enclave termination.

CICS Short-on-Storage Condition

The CICS short-on-storage condition might be raised under Language Environment if functions in your application attempt to acquire storage by using language facilities and not enough storage is available to satisfy the request. CICS places the transaction on a queue until the storage request can be satisfied. If CICS cannot get enough storage in a reasonable amount of time to satisfy the request, then the transaction that issued the storage request is terminated by CICS with abend code AKCP.

CICS Storage Protect Facility

The CICS Storage Protect Facility allows you to isolate user applications from CICS storage. See CICS System Definition Guide and CICS Application Programming Guide for information about the CICS Storage Protect Facility.
Running Applications under CICS

All storage that Language Environment acquires on behalf of the user, such as working storage, heap, and stack, it acquires in the default key specified on the transaction. All storage that Language Environment acquires for its own use, such as control blocks, it acquires using USERDATAKEY storage. Applications running with Language Environment can obtain CICSDATAKEY storage by using the EXEC CICS interface.

PL/I Storage Considerations under CICS

Special storage considerations for running PL/I applications under CICS are described in the following sections.

Initializing Static External Data

You must initialize static external data under CICS because CICS cannot handle common CSECTs.

PL/I Object Program Size

The load module resulting from a PL/I application must not occupy more than 524,152 bytes of main storage. An exception is that an RMODE=ANY program can occupy 16 megabytes, although this is not recommended.

Using CICS Storage Constructs Rather Than PL/I Language Statements

In the case when a PL/I routine (routine A, for example) issues an EXEC CICS LINK to another PL/I routine (routine B, for example), you might want to use EXEC CICS GETMAIN and FREEMAIN commands to get and free storage. This is because the scope of EXEC CICS GETMAIN is the scope of the entire task, not just a single routine. Either routine A or routine B can explicitly free the storage. Alternatively, you can choose to not explicitly free the storage in either routine, but allow the storage to be freed automatically when the task is terminated. Another advantage to using EXEC CICS GETMAIN is that if routine A terminates, the storage is still available to routine B.

When you use PL/I language statements to get and free storage, the scope of PL/I storage statements is the routine, not the task. Although routine B can alter the storage allocated by routine A by using a pointer, routine B cannot free the storage. In addition, if routine A terminates, the storage is automatically freed. Routine B can no longer access the storage.

PL/I Storage Classes

When using CICS, you should avoid altering STATIC storage. Doing so violates reentrancy and can yield unpredictable results. Instead of altering STATIC storage, you should make most or all user variables that are changed while the routine is running AUTOMATIC. Those user variables with initial values that never change should be declared STATIC INITIAL.

Although AUTOMATIC storage provides reentrancy and should suffice for most purposes, you can also allocate and free storage with the ALLOCATE and FREE statements, which you can use to allocate and free BASED and CONTROLLED variables. References you make to BASED storage are handled with the pointer set by the ALLOCATE statement. The pointer itself can be AUTOMATIC.

You can use CONTROLLED storage under CICS, because it is consistent with reentrancy.
Running Applications under CICS

Using PUT DATA with BASED Storage: BASED storage is used extensively in CICS transactions. You therefore need to be aware of the following restriction on PUT DATA.

In PL/I, you cannot code:
```
PUT DATA (P -> VAR);
```

If, however, VAR was declared as BASED (P), the value of the generation of VAR to which P points can be coded as:
```
PUT DATA (VAR);
```

Using Storage Built-In Functions
The STORAGE and CURRENTSTORAGE built-in functions return the length of an item to your PL/I routine. This is useful in CICS, where functions often require the length of an argument as well as its address. In particular, you can use these functions to get lengths of PL/I aggregates without having to count or compute such lengths or specify length fields in the CICS commands.

For more information about the STORAGE and CURRENTSTORAGE built-in functions, see VisualAge PL/I Language Reference and PL/I for MVS & VM Language Reference.

Condition Handling under CICS

The Language Environment condition handling services described in Chapter 15, “Language Environment Condition Handling Introduction,” on page 193 and elsewhere in this book are supported under CICS, but additional considerations apply when running an application under CICS; these considerations are described in the following sections.

Condition handling in nested enclaves created by EXEC CICS LINK or EXEC CICS XCTL is discussed in “How conditions arising in child enclaves are handled” on page 557.

PL/I Considerations for Using the CICS HANDLE ABEND Command
The EXEC CICS HANDLE facility resembles a PL/I ON-unit with this syntax:
```
ON condition GO TO label;
```

You can code the HANDLE command wherever you would code the ON...GO TO...statement. The label to be branched to can be located in any other active block, and the condition can arise in an even later block. HANDLE terminates intervening PL/I blocks by invoking PL/I's out-of-block GO TO facilities.

Note: Because PL/I internal procedures are not active at all times, you should not use internal procedures as exit routines in HANDLE commands.

HANDLE is not semantically identical to the ON condition GO TO label; statement. A PL/I ON-unit disappears when the block containing it terminates; a CICS HANDLE disappears permanently when it is explicitly overridden by another one at the same logical LINK level.

A HANDLE command could specify a branch to a label in a block no longer active. Because HANDLE is implemented by forcing a PL/I out-of-block GO TO, this is equivalent to assigning a label constant to a PL/I label variable after the block containing the label constant has terminated, which is invalid. The PL/I out-of-block
GO TO mechanism attempts to detect this error and raises the ERROR condition. If PL/I out-of-block GO TO fails to detect such an invalid GO TO, however, the GO TO becomes a wild branch that causes some unpredictable failure. Thus, upon return from a PL/I block that established HANDLE for a particular condition, your program should issue a resetting HANDLE for that condition (provided, of course, that there is still some possibility of the condition arising). A PL/I ON-unit does not have to be reset.

Effect of the CICS HANDLE ABEND Command

When an application is running under CICS with Language Environment, condition handling differs depending on whether a CICS HANDLE ABEND is active or not active.

When a CICS HANDLE ABEND is active, Language Environment condition handling does not gain control for any abends or program interrupts. Any abends or program interrupts that occur while a CICS HANDLE ABEND is active cause the action defined in the CICS HANDLE ABEND to take place. The user-written condition handlers established by CEEHDLR are ignored.

When a CICS HANDLE ABEND is not active, Language Environment condition handling does gain control for abends and program interrupts if the TRAP(ON) option is specified. Normal Language Environment condition handling is then performed.

Effect of the CICS HANDLE CONDITION and CICS HANDLE AID

Language Environment condition handling does not alter the behavior of applications that use CICS HANDLE CONDITION or CICS HANDLE AID. The CICS CONDITION and AID conditions are raised by CICS and are handled only by CICS; Language Environment is not involved in the handling of CICS conditions.

Restrictions on User-Written Condition Handlers under CICS

The following EXEC CICS commands cannot be used within a user-written condition handler established using CEEHDLR, or within any routine called by the user-written condition handler:

- EXEC CICS ABEND
- EXEC CICS HANDLE AID
- EXEC CICS HANDLE ABEND
- EXEC CICS HANDLE CONDITION
- EXEC CICS IGNORE CONDITION
- EXEC CICS POP HANDLE
- EXEC CICS PUSH HANDLE

All other EXEC CICS commands are allowed within a user-written condition handler. However, they must be coded using the NOHANDLE option, the RESP option, or the RESP2 option. This prevents additional conditions being raised due to a CICS service failure.

COBOL Considerations

A user-written condition handler registered for a routine using the CEEHDLR service cannot be translated using the CICS translator and therefore cannot contain any EXEC CICS commands. This is because the CICS translator inserts (onto the PROCEDURE DIVISION header of the COBOL program) the arguments EXEC Interface Block (EIB) and COMMAREA, which do not match arguments passed by Language Environment.
Running Applications under CICS

However, a user-written condition handler can call a subroutine to perform EXEC CICS commands. If arguments need to be passed to this subroutine, they should be preceded by two dummy arguments in the caller. The called subroutine must issue EXEC CICS ADDRESS EIB before executing any other EXEC CICS commands.

CICS Transaction Abend Codes

The same Language Environment reserved abend codes (4000 through 4095) are used for applications running under CICS. In addition, there are special reason codes returned to CICS for severe Language Environment conditions. These severe conditions are CICS-specific. For a detailed explanation of these reason codes, see z/OS Language Environment Run-Time Messages.

Using the CBLPSHPOP Run-Time Option under CICS

This section applies to Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, and VS COBOL II programs only.

The CBLPSHPOP run-time option controls whether the Language Environment environment automatically issues an EXEC CICS PUSH HANDLE command during initialization and an EXEC CICS POP HANDLE command during termination whenever a COBOL subroutine is called.

If your application calls COBOL subroutines under CICS, your application performance is better with CBLPSHPOP(OFF) than with CBLPSHPOP(ON). You can set CBLPSHPOP on a transaction-by-transaction basis by using CEEUOPT.

For more information about CBLPSHPOP, see z/OS Language Environment Programming Reference.

Restrictions on Assembler User Exits under CICS

The following EXEC CICS commands cannot be used within the assembler user exit or any routines called by the assembler user exit:

- EXEC CICS ABEND
- EXEC CICS HANDLE AID
- EXEC CICS HANDLE ABEND
- EXEC CICS HANDLE CONDITION
- EXEC CICS PUSH HANDLE
- EXEC CICS POP HANDLE
- EXEC CICS IGNORE CONDITION

All other EXEC CICS commands are allowed within the assembler user exit. However, they must be coded using the NOHANDLE option, the RESP option, or the RESP2 option. This prevents additional conditions being raised due to a CICS service failure.

PL/I Considerations

You can use PLIRETC to communicate with the Language Environment assembler user exit. For more information about PLIRETC, see For PL/I on page 153. For more information about the assembler user exit, see Chapter 28, “Using Run-Time User Exits,” on page 457.
Ensuring Transaction Rollback under CICS

Conditions that occur while an application is executing under CICS can potentially contaminate any database currently being used by the application. It is essential that a rollback (the backing out of any updates made by the failing application) be performed before further damage to the database can occur.

There are two ways to ensure that a transaction rollback occurs when an unhandled condition of severity 2 or greater is detected:

- Use the ABTERMENC(ABEND) run-time option, or
- Make sure the assembler user exit requests an abend for unhandled conditions of severity 2 or greater.

Run-Time Output under CICS

Language Environment provides the same message handling and dump services for CICS as it does for non-CICS systems. Any exceptions to this support under CICS are noted in the following sections.

Message Handling under CICS

The MSGFILE run-time option is ignored under CICS, because messages for a run unit are directed instead to the CICS transient data queue named CESE.

Messages are prefixed by a terminal ID, a transaction ID, a date, and a timestamp before their transmission. Figure 158 illustrates this format.

<table>
<thead>
<tr>
<th>ASA</th>
<th>Terminal ID</th>
<th>Transaction ID</th>
<th>sp</th>
<th>Time Stamp</th>

</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4</td>
<td>4</td>
<td>1</td>
<td>YYYYMMDDHHMMSS</td>
<td>1</td>
<td>132</td>
</tr>
</tbody>
</table>

*Figure 158. Format of Messages Sent to CESE*

Terminal ID A 4-character terminal identifier.

Transaction ID A 4-character transaction identifier.

sp A space.

Timestamp The date and time displayed in the same format as that returned by the CEELOCT service.
Running Applications under CICS

Message
The message identifier and message text.

The entire message record is preceded by an ASCII control character to determine the format of the printing.

Message records are V-format.

PL/I SYSPRINT
PL/I SYSPRINT also uses the CESE transient data queue. For information on how to declare SYSPRINT, see VisualAge PL/I for OS/390 Programming Guide or PL/I for MVS & VM Programming Guide.

Dump Services under CICS
Under CICS, the FNAME parameter of the CEE3DMP callable service is ignored. Instead of being written to a ddname specified in FNAME, dumps are instead transmitted to the CICS transient data queue named CESE.

The dump is prefixed with the same information shown in Figure 158 on page 445.

PL/I Considerations
The PLIDUMP subroutine has two additional options under CICS and some special considerations. For more information about PLIDUMP, see z/OS Language Environment Debugging Guide.

Support for Calls within the Same HLL under CICS
For ILC information while running under CICS, see z/OS Language Environment Writing Interlanguage Communication Applications.

C
EXEC CICS LINK, EXEC CICS XCTL, and calls via fetch() and DLL are supported under CICS. The fetched program or DLL must be defined in the CSD and installed in the PPT. For more information, see z/OS C/C++ Programming Guide.

C++
EXEC CICS LINK, EXEC CICS XCTL, and dynamic calls via DLL are supported under CICS. The DLL must be defined in the CSD and installed in the PPT. For further information, see z/OS C/C++ Programming Guide.

COBOL
The following sections describe support for calls compiled under different versions of COBOL compilers.

Language Environment-conforming COBOL
Static and dynamic calls between Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, and VS COBOL II programs are supported as follows:
- Called programs can contain any command or facility supported by CICS for COBOL.
• If the called program has been translated by the CICS translator, calling programs must pass the EIB and COMMAREA as the first two parameters on the CALL statement.

Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM and COBOL/370 programs can invoke or be invoked by OS/VS COBOL programs only through CICS facilities such as EXEC CICS LINK, EXEC CICS XCTL, and EXEC CICS RETURN.

**VS COBOL II**

Static and dynamic calls to or from Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, and VS COBOL II programs are supported with the same considerations previously listed.

VS COBOL II programs can communicate with OS/VS COBOL programs only through CICS facilities such as EXEC CICS LINK, EXEC CICS XCTL, and EXEC CICS RETURN.

**OS/VS COBOL**

OS/VS COBOL programs cannot directly call or be called from Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, or VS COBOL II programs. The only programs that can be called from OS/VS COBOL are other OS/VS COBOL programs, and with the following restrictions:

• The call must be a static CALL
• The subprogram cannot contain EXEC CICS statements.

**PL/I**

Static calls are supported from any version of PL/I. Called subroutines can invoke CICS services if the address of the EIB is passed to the subroutine properly. You can do this by setting up the address of the EIB yourself and passing it to the subroutine, or by coding the following command in the subroutine before issuing any other CICS commands.

EXEC CICS ADDRESS EIB(DFHEIPTR)

PL/I FETCH is supported under CICS in a PL/I transaction compiled with VisualAge PL/I and PL/I for MVS & VM. CICS does not support PL/I MTF applications.
Chapter 26. Running Applications under DB2

This chapter describes Language Environment support for DB2 applications.

Understanding the Basics

An application program requests DB2 services by using SQL statements imbedded in the program. The imbedded SQL is translated by the SQL pre-compiler into host language statements that typically perform assignments and then call a DB2 language interface module. The same entry point of the module is called by all Language Environment-conforming languages. DB2 processes the request and then returns to the application.

Language Environment Support for DB2 Applications

You are not required to modify anything in your code to run a Language Environment-conforming application with DB2. Language Environment also supports ILC applications that use DB2 services.

Language Environment supports XPLINK applications that use DB2 services, but does not support XPLINK-compiled DB2 stored procedures.

Condition Handling under DB2

Any errors occurring in DB2 are trapped by DB2 and handled properly. If a task terminates, DB2 takes appropriate action depending on the nature of termination.

The Language Environment run-time user exits can be used by the installation to effect abnormal termination, and therefore database rollbacks, of applications.

For information about additional HLL restrictions under DB2, see the Application Programming Guide for your HLL listed in “Bibliography” on page 635. For more information about using DB2 services, see Database 2 Application Programming and SQL Guide.

PL/I Consideration for DB2 Applications

PL/I multitasking applications are not supported under DB2. PL/I multitasking applications support DB2 SQL statements from multiple tasks only in non-CICS and non-IMS environments.
Chapter 27. Running Applications under IMS

This chapter describes Language Environment support for applications running under IMS/ESA Version 3 Release 1 and later.

Understanding the Basics

You do not need to change any of the code in your application in order to run under IMS/ESA, but there are a number of restrictions and recommendations that you should consider. Two of these concerns include ensuring proper condition handling under IMS and running your application in an IMS/ESA environment. These topics, together with an overview of how Language Environment interacts with IMS, are discussed in detail below.

For a detailed description of how to write IMS batch and online applications, see the IMS Application Programming Guide appropriate to your version of IMS as listed in "Bibliography" on page 635.

Using the Interface between Language Environment and IMS

Language Environment provides a callable service, CEETDLI, that you can use to invoke IMS (Version 4 or later) facilities. In assembler, COBOL, PL/I, C and C++, you can also invoke IMS by using the following interfaces:
- In assembler, the ASMTDLI interface
- In COBOL, the CBLTDLI interface
- In PL/I, the PLITDLI interface
- In C or C++, the CTDLI interface (a ctdli() function call)
- In C or C++ (including XPLINK-compiled functions), the CTDLI interface (a ctdli() function call)

Under Language Environment, each of these interfaces continues to function in its current capacity. CEETDLI performs essentially the same functions, but it offers some advantages, particularly if you plan to run an ILC application in IMS. For example, if you use CEETDLI, you get coordinated condition handling between Language Environment and IMS condition handling facilities. For more information, see "Coordinated Condition Handling under IMS" on page 453.

CEETDLI supports calls that use an application interface block (AIB) or a program communication block (PCB). For more information about AIB and a complete description of all available IMS functions and argument parameters you can specify in CEETDLI, see an IMS Application Programming Guide listed in the "Bibliography" on page 635.

Appendix B, “EXEC DL/I and CALL IMS Interfaces,” on page 589 lists various DL/I interfaces and the support for them under CICS and IMS. For information about CEETDLI, including its syntax and examples, see z/OS Language Environment Programming Reference.

z/OS C/C++ Considerations under IMS

To interface with IMS from z/OS C/C++, you must do the following:
- Specify the PLIST(OS), ENV(IMS), and NOEXECOPS run-time options of #pragma runopts in your source code. The PLIST(OS) option establishes the correct parameter list format when invoked under IMS. The ENV(IMS) option
Running Applications under IMS

establishes the correct operating environment. The NOEXECOPS option specifies that run-time options cannot be specified for IMS.

• When you use the PLIST(OS) option in #pragma runopts, argc contains 1 (one) and argv[0] contains NULL.

For more information about using the #pragma runopts preprocessor directive, see Chapter 9, “Using Run-Time Options,” on page 117.

Applications that use the POSIX(ON) run-time option are supported under IMS only if they consist of a single thread. Calls to z/OS UNIX threading functions are restricted under IMS. See z/OS C/C++ Programming Guide for a list of restrictions on running z/OS C/C++ programs under IMS with z/OS UNIX.

C++ Considerations under IMS

To interface with IMS from C++, you must do the following:

• For any C++ program that runs under IMS, you must specify the TARGET(IMS) compiler option.

• For any C++ program that is the initial main() called under IMS, you must specify the PLIST(OS) compiler option.

• For any C++ programs in nested enclaves, you need only specify the TARGET(IMS) compiler option.

PL/I Considerations under IMS

With IMS/ESA Version 4, PL/I supports PSBs with LANG=PLI and all others (including LANG=blank), except LANG=Pascal. With IMS/ESA Version 3 Release 1, PL/I supports PSBs with LANG=PLI only.

The SYSTEM(IMS) compiler option must be specified for PL/I applications running under IMS. When SYSTEM(IMS) is specified, the OPTIONS(BYVALUE) attribute is implied for any external PROCEDURE that also has OPTIONS(MAIN). Further, the parameters to such a MAIN procedure must be POINTERS.

With IMS/ESA Version 3 Release 1 and Version 4, the parameters passed to language-IMS CALL interfaces such as PLITDLI are no longer required to be below the 16M line.

If an assembler program is driving a transaction program written in VisualAge PL/I or PL/I for MVS & VM, the main procedure of the transaction must be compiled with SYSTEM(MVS) option; the main procedure receives the parameter list passed from the assembler program in MVS style. IMS does not support PL/I MTF applications.

IMS Communication with Your Application

When you run your application under IMS, IMS loads the application and passes it the invocation parameter list. A PSB is automatically scheduled for every application you run under IMS. IMS/ESA Version 4 always constructs the parameter list in the same format, regardless of the setting of the LANG= option in the PSB. The LANG= option has no effect on the format of the parameter list that IMS constructs. Thus, any PSB can be used with any HLL application in Language Environment.

Beginning with IMS/ESA Version 4, the LANG= option in the PSB statement is not required.
Before your application is loaded, it is link-edited with an IMS language interface module, DFSLI000. Any calls that your application makes with CEETDLI for IMS services end up in this module. DFSLI000, in turn, invokes the services and returns IMS replies to your application.

**Link-Edit Considerations under IMS**

Unless your application communicates with IMS exclusively via dynamic calls to the CEETDLI callable service, DFSLI000 must be link-edited with your application code. Therefore, under MVS, ensure that DFSLI000 appears in a partitioned data set that is specified in the SYSLIB DD statement in the JCL used to link-edit the application.

You must be using IMS Version 4 or later if you want to use the CEETDLI callable service. Errors occur if you attempt to use the CEETDLI callable service and you are not running IMS Version 4.

**Making Your IMS Application Reentrant**

For many IMS users, the storage required at run time for any given IMS transaction can be fairly large. Therefore, the most efficient method of coding an application is to make it reentrant. This method can eliminate application loading time, speed up IMS initialization and restart, and provide the additional integrity that results from having your routines in protected storage.

Methods for making your application reentrant differ across HLLs. For more information, see Chapter 11, “Making Your Application Reentrant,” on page 139.

**Condition Handling under IMS**

The IMS environment is sensitive to errors or conditions. A failing IMS transaction or application can potentially contaminate an IMS database. For this reason, it is essential that IMS know about the failure of a transaction or application that has been updating a database so that it can perform database rollback (the backing out of any updates made by the failing application).

**Coordinated Condition Handling under IMS**

Language Environment and IMS condition handling is coordinated, meaning that if a program interrupt or abend occurs when your application is running in an IMS environment, the Language Environment condition manager can determine whether the problem occurred in your application or in IMS. If the program interrupt or abend occurs in IMS, Language Environment, as well as any invoked HLL-specific condition handler, percolates the condition back to IMS.

If a program interrupt or abend occurs in the application outside of IMS, or if a software condition of severity 2 or greater is raised outside of IMS, the Language Environment condition manager takes normal condition handling actions as described in Chapter 15, “Language Environment Condition Handling Introduction,” on page 193. If the condition manager remains in control, however, you must do one of the following:

- Resolve the error completely so that the application can continue.
- Issue a rollback call to IMS, and then terminate the application.
- Ensure the application terminates abnormally by using the ABTERMENC(ABEND) run-time option to transform all abnormal terminations into operating system abends in order to cause IMS rollbacks.
Running Applications under IMS

- Ensure the application terminates abnormally by coding and providing a modified run-time assembler user exit (CEEBXITA) that transforms all abnormal terminations into operating system abends in order to cause IMS rollbacks.

  The assembler user exit you provide should check the return code and reason code or the CEEAUE_ABTERM bit, and request an abend by setting the CEEAUE_ABND flag to ON, if appropriate. See "CEEBXITA Assembler User Exit Interface" on page 463 for more details about the CEEBXITA user exit.

Diagnosing Abends with the IMS Dump

If an interrupt or abend occurs in IMS, you can use the IMS dump (which contains the information that is available at the time of the program interrupt or abend) for diagnosis. You can also use the Language Environment dump (CEEDUMP) for diagnosis.

If the interrupt or abend occurs in your application (outside of IMS), the IMS dump shows the state of the system after Language Environment gained control, did some cleanup of the environment, and requested the abend. In this case, you can use only the Language Environment dump (CEEDUMP) for diagnosis.
Part 5. Specialized Programming Tasks

The chapters in this section describe advanced or specialized tasks that you can perform in Language Environment.
Chapter 28. Using Run-Time User Exits

Language Environment provides user exits that you can use for functions at your installation. You can use the assembler user exit (CEEBXITA) or the HLL user exit (CEEBINT). This chapter provides information about using these run-time user exits.

Understanding the Basics

User exits are invoked under Language Environment to perform enclave initialization functions and both normal and abnormal termination functions. User exits offer you a chance to perform certain functions at a point where you would not otherwise have a chance to do so. In an assembler initialization user exit, for example, you can specify a list of run-time options that establish characteristics of the environment. This is done prior to the actual execution of any of your application code.

In most cases, you do not need to modify any user exit in order to run your application. Instead, you can accept the IBM-supplied default versions of the exits, or the defaults as defined by your installation. To do so, run your application in the normal manner and the default versions of the exits are invoked. You might also want to read the sections “User Exits Supported under Language Environment” and “When User Exits Are Invoked” on page 460, which provide an overview of the user exits and describe when they are invoked.

If you plan to modify either of the user exits to perform some specific function, you must link the modified exit to your application before running. In addition, the sections “Using the Assembler User Exit CEEBXITA” on page 458 and “CEEBINT High-Level Language User Exit Interface” on page 470 describe the respective user exit interfaces to which you must adhere in order to change an assembler or HLL user exit.

User Exits Supported under Language Environment

Language Environment provides two user exit routines, one written in assembler (CEEBXITA), and the other in a Language Environment-conforming language or Fortran (CEEBINT). You can find sample jobs containing these user exits in the SCEESAMP sample library.

The user exits supported by Language Environment are shown in Table 56.

Table 56. User Exits Supported under Language Environment

<td>Enclave initialization</td>
</tr>
</tbody>
</table>
Run-Time User Exits

functions as an application-specific user exit. The application-specific exit is used only when you run that application. The installation-wide assembler user exit is not executed.

When your version of CEEBINT is linked with the Language Environment library routines during installation, this version is automatically used at link-edit time for newly built or relinked applications. A new version of CEEBINT will require you to relink your application.

To use an application-specific user exit, you must explicitly include it at link-edit time in the application load module using an MVS INCLUDE link-edit control statement (see “Using the INCLUDE Statement” on page 76 for more information). Any time that the application-specific exit is modified, it must be relinked with the application.

The assembler user exit interface is described in CEEBXITA Assembler User Exit Interface on page 463. The HLL user exit interface is described in CEEBINT High-Level Language User Exit Interface on page 470.

Using the Assembler User Exit CEEBXITA

CEEBXITA tailors the characteristics of the enclave prior to its establishment. It must be written in assembler language because an HLL environment is not yet established when the exit is invoked. You cannot code CEEBXITA as an XPLINK application. However, since CEEBXITA is called directly by Language Environment and not by the application, a non-XPLINK CEEBXITA can be statically bound in the same program object with an XPLINK application. CEEBXITA is driven for enclave initialization and enclave termination regardless of whether the enclave is the first enclave in the process or a nested enclave. CEEBXITA can differentiate easily between first and nested enclaves. For more information about nested enclaves, see Chapter 31, “Using nested enclaves,” on page 555.

CEEBXITA is invoked very early during the initialization process, before enclave initialization is complete. The enclave initialization code recognizes run-time options contained in CEEBXITA.

The assembler user exit is supported with POSIX(ON) and in a threaded environment. Within a given Language Environment process, the following functions are driven on the initial thread:

- Initialization of the first enclave within a process
- Termination of the first enclave within a process
- Termination of the process

For nested enclaves, the following functions are driven:

- Nested enclave initialization
- Nested enclave termination

The abend percolation list is applied to all threads in the enclave as specified in the assembler user exit.

Using the HLL Initialization Exit CEEBINT

CEEBINT is invoked just before the invocation of the application code. Under Language Environment, this exit can be written in C, C++, Fortran, PL/I, or in Language Environment-conforming assembler. When CEEBINT is written in C++, it must be declared as extern "C" in the C++ source. CEEBINT cannot be written in COBOL, even though COBOL applications can use this HLL user exit. You cannot code CEEBXITA as an XPLINK application. However, since CEEBXITA is called
directly by Language Environment and not the application, a non-XPLINK
CEEBXITA can be statically bound in the same program object with an XPLINK
application. When CEEBINT is invoked, the run-time environment is fully operational
and all Language Environment-conforming HLLs are supported.

PL/I and C Compatibility
The following OS PL/I Version 2 Release 3 user exits are supported for
compatibility under Language Environment:
• IBMBXITA (z/OS Batch version)
• IBMFXITA (CICS version)

Note: VisualAge PL/I does not support the IBMBXITA, IBMFXITA and IBMINT
user exits.

For information about IBMBXITA and IBMINT, see Enterprise PL/I for z/OS and
OS/390 Migration Guide or z/OS C/C++ Programming Guide.

Default versions of these user exits are not supplied under Language Environment;
instead, Language Environment supplies a default version of CEEBXITA.

Table 57 describes the order of precedence if the IBMBXITA and IBMFXITA user
exits are found in the same root load module with CEEBXITA.

Table 57. Interaction of Assembler User Exits

Using Sample Assembler User Exits
You can use the sample assembler user exit programs distributed with Language
Environment to modify the code for the requirements of your application. Choose a
sample program appropriate for your application. The following assembler user exit
programs are delivered with Language Environment:

Table 58. Sample Assembler User Exits for Language Environment

</tbody>
</table>
Run-Time User Exits

If you install Language Environment at your site without modifying it, your system defaults are CEEBXITA and CEECXITA for MVS and CICS. You can find the source code for CEEBXITA, CEEBXITC, CEECXITA, and CEEBX05A on MVS in the sample library SCEESAMP.

The assembler user exit CEEBXITA performs functions for enclave initialization, normal and abnormal enclave termination, and process termination. CEEBXITA must be written in assembler language, because an HLL environment might not be established when the exit is invoked.

You can set up user exits for tasks such as:
- Installation accounting and charge back
- Installation audit controls
- Programming standard enforcement
- Common application run-time support

When User Exits Are Invoked

Figure 159 shows the timing of the invocations of the user exits at initialization and termination processing.

In Figure 159, run-time user exits are invoked in the following sequence:
1. Assembler user exit is invoked for enclave initialization.
2. Environment is established.
3. HLL user exit is invoked.
4. Main routine is invoked.
5. Main routine returns control to caller.
6. Assembler user exit is invoked for termination of the enclave. CEEBXITA is invoked for enclave termination processing after all application code in the enclave has completed, but prior to any enclave termination activity.
7. Environment is terminated.
8. Assembler user exit is invoked for termination of the process. CEEBXITA is invoked again when the Language Environment process terminates.

Language Environment provides the CEEBXITA assembler user exit for termination but does not provide a corresponding HLL termination user exit.

CEEBXITA behaves differently, depending upon when it is invoked, as described in the following sections.

**CEEBXITA Behavior During Enclave Initialization**

The CEEBXITA assembler user exit is invoked before enclave initialization is performed. You can use CEEBXITA to help establish your application run-time environment. For example, in the assembler user exit you can specify the stack and heap run-time options and allocate data sets. You can also use the user exit to interrogate program parameters supplied in the JCL and change them if you want. In addition, you can specify run-time options in the user exit by using the CEEAUE_A_OPTIONS field of the assembler interface.

CEEBXITA returns control to Language Environment initialization.

**CEEBXITA Behavior During Enclave Termination**

The CEEBXITA assembler exit is invoked after the user code for the enclave has completed, but prior to the occurrence of any enclave termination activity. In other words, the assembler user exit for termination is invoked when the environment is still active. For example, CEEBXITA is invoked before the storage report is produced (if you requested one), data sets are closed, and CODE is invoked for enclave termination.

The assembler user exit permits you to request an abend. You can also request a dump to assist in problem diagnosis. Because termination activities have not yet begun when the user exit is invoked, the majority of storage has not been modified when the dump is produced.

You can request the abend and dump in the assembler user exit for all enclave-terminating events including:

- The situation that occurs in PL/I when the ON condition (including ERROR or FINISH) is raised and one of the following conditions is true:
  - The program does not have an appropriate ON-unit.
  - The ON-unit does not terminate with a GOTO.
  - The GOTO is not allowed.

  This rule applies only to the conditions that cause termination of the program.

- Return from the main routine
- A Debug Tool QUIT command
Run-Time User Exits

- An HLL stop statement such as:
  ```
  C exit()
  COBOL STOP RUN
  PL/I STOP or EXIT
  Fortran STOP
  ```
- An unhandled condition of severity 2 or above

If a dump is requested in the user assembler exit and an unhandled condition has occurred, this dump will overwrite the dump taken by TERMTHD(ACT(UADUMP)).

**CEEBXITA Behavior During Process Termination**

The CEEBXITA assembler exit is invoked after:
- All enclaves have terminated
- The enclave resources have been relinquished
- Any Language Environment-managed files have been closed
- Debug Tool has terminated

At this time you can free allocated files and request an abend.

During termination, CEEBXITA can interrogate the Language Environment reason and return codes and, if necessary, request an abend with or without a dump. This can be done at either enclave or process termination.

**Specifying Abend Codes to Be Percolated by Language Environment**

The assembler user exit, when invoked for initialization, might return a list of abend codes (contained in the CEEAUE_A_AB_CODES field of the assembler user exit interface—see "CEEBXITA Assembler User Exit Interface" on page 463) that are to be percolated by Language Environment.

On non-CICS systems, this list is contained in the CEEAUE_A_AB_CODES field of the assembler user exit interface. (See "CEEBXITA Assembler User Exit Interface" on page 463.) Both system abends and user abends can be specified in this list. The abend percolation list specified in the assembler user exit applies to all threads in the enclave.

When TRAP(ON) is in effect, and the abend code is in the CEEAUE_A_AB_CODES list, Language Environment percolates the abend. Normal Language Environment condition handling is never invoked to handle these abends. This feature is useful when you do not want Language Environment condition handling to intervene for certain abends, such as when IMS issues a user ABEND code 777.

When TRAP(OFF) is specified and there is a program interrupt, the user exit for termination is not driven.

**Actions Taken for Errors That Occur within the Exit**

If any errors occur during the enclave initialization user exit, the standard system action occurs because Language Environment condition handling has not yet been established.

Any errors occurring during the enclave termination user exit lead to abnormal termination (through an abend) of the Language Environment environment.

If there is a program check during the enclave termination user exit and TRAP(ON) is in effect, the application ends abnormally with ABEND code 4044 and reason
code 2. If there is a program check during the enclave termination user exit and TRAP(OFF) has been specified, the application ends abnormally without additional error checking support. Language Environment performs no condition handling; error handling is performed by the operating system.

Language Environment takes the same actions as described above for program checks during the process termination user exit.

### CEEBXITA Assembler User Exit Interface

You can modify CEEBXITA to perform any function you need, but the exit must have the following attributes after you modify it at installation:

- The user-supplied exit must be named CEEBXITA.
- The exit must be reentrant.
- The exit must be capable of executing in AMODE(ANY) and RMODE(ANY).
- The exit must be relinked with Language Environment initialization/termination routines after modification.

If a user exit is modified, you are responsible for conforming to the interface shown in Figure 160. Note that this user exit must be written in assembler. You cannot code CEEBINT as an XPLINK application. However, since CEEBINT is called directly by Language Environment and not the application, a non-XPLINK CEEBINT can be statically bound in the same program object with an XPLINK application.

**Figure 160. Interface for CEEBXITA Assembler User Exit**

When the user exit is called, register 1 points to a word that contains the address of the CEEAUE control block. The high-order bit is on.
The CEEAUE control block contains the following fullwords:

**CEEAUE_LEN** (input parameter)
A fullword integer that specifies the total length of this control block. For Language Environment, the length is 48 bytes.

**CEEAUE_FUNC** (input parameter)
A fullword integer that specifies the function code. Language Environment supports the following function codes:
1. Initialization of the first enclave within a process.
2. Termination of the first enclave within a process.
5. Process termination.

The user exit should ignore function codes other than those numbered from 1 through 5.

**CEEAUE_RETC** (input/output parameter)
A fullword integer that specifies the return or abend code. CEEAUE_RETC has different meanings, depending on CEEAUE_ABND:
- If the flag CEEAUE_ABND (see below) is off, this fullword is interpreted as the Language Environment return code placed in register 15.
- If the flag CEEAUE_ABND is on, CEEAUE_RETC is interpreted as an abend code used when an abend is issued. (This could be either an EXEC CICS ABEND or an SVC13.)

**CEEAUE_RSNC** (input/output parameter)
A fullword integer that specifies the reason code for CEEAUE_RETC:
- If the flag CEEAUE_ABND (see below) is off, this word is interpreted as the Language Environment reason code placed in register 0.
- If the flag CEEAUE_ABND is on, CEEAUE_RETC is interpreted as an abend reason code used when an abend is issued.

This field is ignored when an EXEC CICS ABEND is issued.

**CEEAUE_FLAGS**
Contains four 1-byte flags. CEEBXITA uses only the first byte but reserves the remaining flags. All unspecified bits and bytes must be 0. The layout of these flags is shown in Figure 161 on page 465.

---

Figure 161. CEEAUE_FLAGS Format

Byte 0 (CEEAUE_FLAG1) has the following meaning:

**CEEAUE_ABTERM** (input parameter)

- **OFF** Indicates that the enclave is terminating normally (severity 0 or 1 condition).
- **ON** Indicates that the enclave is terminating with an Language Environment return code modifier of 2 or greater. This could, for example, indicate that a severity 2 or greater condition was raised but not handled.

**CEEAUE_ABND** (input/output parameter)

- **OFF** Indicates that the enclave should terminate without an abend being issued. Thus, CEEAU_RETC and CEEAU_RSNC are placed into register 15 and register 0 and returned to the enclave creator.
- **ON** Indicates that the enclave terminates with an abend. Thus, CEEAU_RETC and CEEAU_RSNC are used by Language Environment in the invocation of the abend. During running in CICS, an EXEC CICS ABEND command is issued.

The TRAP run-time option does not affect the setting of CEEAUE_ABND.

When the ABTERMENC(ABEND) run-time option is specified, the enclave always terminates with an abend when there is an unhandled condition of severity 2 or greater, regardless of the setting of the CEEAUE_ABND flag. See [Termination behavior for unhandled conditions](#) on page 154 for a detailed explanation of how the CEEAUE_ABND parameter can affect the behavior of the ABTERMENC run-time option.

**CEEAUE_DUMP** (output parameter)

- **OFF** Indicates that when you request an abend, an abend is issued without requesting a dump.
- **ON** Indicates that when you request an abend, an abend requesting a dump is issued.

**CEEAUE_STEPS** (output parameter)
Run-Time User Exits

OFF Indicates that when you request an abend, an abend is issued to abend the entire TASK.

ON Indicates that when you request an abend, an abend is issued to abend the STEP.

This parameter is ignored under CICS.

**CEEAU E_A_CC_PLIST** (input/output parameter)
A fullword pointer to the parameter address list of the application program.

If the parameter is not a character string, CEEAU E_A_CC PLIST contains the register 1 value as passed by the calling program or operating system at the time of program entry.

If the parameter inbound to the MAIN routine is a character string, CEEAU E_A_CC PLIST contains the address of a fullword address that points to a halfword prefixed string. If this string is altered by the user exit, the string must not be extended in place.

**CEEAU E_WORK** (input parameter)
A fullword pointer to a 256-byte work area that the exit can use. On entry it contains binary zeros and is doubleword-aligned.

This area does not persist across exits.

**CEEAU E_A_OPTIONS** (output parameter)
Upon return, this field contains a fullword pointer to the address of a halfword-length prefixed character string that contains run-time options. These options are honored only during the initialization of an enclave. When invoked for enclave termination, this field is ignored.

These run-time options override all other sources of run-time options except those that are specified as NONOVR in the installation default run-time options.

Under CICS, the STACK run-time option cannot be modified with the assembler user exit.

**CEEAU E_USERWD** (input/output parameter)
A fullword whose value is maintained without alteration and passed to every user exit. Upon entry to the enclave initialization user exit, it is zero. Thereafter, the value of the user word is not altered by Language Environment or any member libraries. The user exit might change the value of this field, and Language Environment maintains that value. This allows the user exit to acquire a work area, initialize it, and pass it to subsequent user exits. The work area might be freed by the termination user exit.

**CEEAU E_A_AB_CODES** (output parameter)
During the initialization exit, this field contains a fullword address of a table of abend codes that the Language Environment condition handler percolates while in the (E)STAE exit. Therefore, the application does not have the chance to address the abend. This table is honored prior to shunt routines. The table consists of:
• A fullword count of the number of abend codes that are to be percolated
• A fullword for each of the particular abend codes that are to be percolated

The abend codes might be either user abend codes or system abend codes. User abend codes are specified by F’uuu’. For example, if you want to percolate user ABEND 777, a F’777’ would be coded. System abend codes are specified by X’00sss000’.

This parameter is not enabled under CICS.
**CEEAUE_FBCODE** (input parameter)
Contains a fullword address of the condition token with which the enclave terminated. If the enclave terminates normally (that is, not due to a condition), the condition token is zero.

**CEEAUE_PAGE** (input parameter)
This parameter indicates whether PL/I BASED variables that are allocated storage outside of AREAs are allocated on a 4K-page boundary. You can specify in the field the minimum number of bytes of storage that must be allocated. Your allocation request must be an exact multiple of 4 KB.

The IBM-supplied default setting for CEEAUE_PAGE is 32768 (32 KB).

If CEEAUE_PAGE is set to zero, PL/I BASED variables can be placed on other than 4K-page boundaries.

CEEAUE_PAGE is honored only during enclave initialization, that is, when CEEAUE_FUNC is 1 or 3.

The offset of CEEAUE_PAGE under Language Environment is different than under OS PL/I Version 2 Release 3.

---

**Parameter Values in the Assembler User Exit**

The parameters described in "CEEBXITA Assembler User Exit Interface" on page 463 contain different values depending on how the user exit is used. Table 59 and Table 60 on page 469 describe the possible values for the parameters based on how the assembler user exit is invoked.

Table 59. Parameter Values in the Assembler User Exit (Part 1). The assembler user exit contains these parameter values depending on when it is invoked.

Process Termination —
Return
If CEEAUAE_ABND = 0, return code from the process.
If CEEAUAE_ABND = 1, the abend code.
If CEEAUAE_ABND = 0, the reason code for CEEAUAE_RETC from the process.
If CEEAUAE_ABND = 1, reason code for the CEEAUAE_RETC abend reason code.

Notes:

1. **CEEAUE_FLAGS:**
   - CEEAUAE_ABND = 1 if an abend is requested, or 0 if the enclave should continue with termination processing
   - CEEAUAE_DUMP = 1 if the abend should request a dump
   - CEEAUAE_STEPS = 1 if the abend should request a dump
   - CEEAUAE_STEPS = 0 if the abend should not request a dump

2. **CEEAUE_FLAGS:**
   - CEEAUAE_ABTERM = 1 if the application is terminating with an Language Environment return code modifier of 2 or greater, or 0 otherwise
   - CEEAUAE_ABND = 1 if an abend is requested, or 0 if the enclave should continue with termination processing
   - CEEAUAE_DUMP = 0
   - CEEAUAE_STEPS = 0

3. **CEEAUE_FLAGS:**
   - CEEAUAE_ABTERM = 1 if the last enclave is terminating abnormally (that is, a Language Environment return code modifier is 2 or greater). This reflects the value returned from the “first enclave within process termination”.
   - CEEAUAE_ABND = 1 if an abend is requested, or 0 if the enclave should continue with termination processing
   - CEEAUAE_DUMP = 0
   - CEEAUAE_STEPS = 0

CEEBINT High-Level Language User Exit Interface

Language Environment provides CEEBINT for enclave initialization. You can code CEEBINT in non-XPLINK C and C++, Fortran, PL/I, or Language Environment-conforming assembler. You cannot code CEEBINT as an XPLINK application. However, since CEEBINT is called directly by Language Environment and not the application, a non-XPLINK CEEBINT can be statically bound in the same program object with an XPLINK application. COBOL programs can use CEEBINT, but CEEBINT cannot be written in COBOL or be used to call COBOL programs.

CEEBINT is supported with POSIX(ON) and in a threaded environment. It is driven only on the initial thread.
Run-Time User Exits

You can modify CEEBINT to perform any function desired, although the exit must have the following attributes after you modify it:

- The user exit must not be a main-designated routine. That is, it must not be a C or C++ main function, and OPTIONS(MAIN) must not be specified for PL/I applications.
- CEEBINT must be linked with compiled code. If you do not provide an initialization user exit, an IBM-supplied default, which simply returns control to your application, is linked with the compiled code. When written in C++, CEEBINT must be linked with your application and it can only function as an application-specific user exit.
- The exit cannot be written in COBOL.
- When CEEBINT is written in C++, it must be declared as extern "C" in the C++ source.
- The exit should be coded so that it returns for all unknown function codes.
- C or C++ constructs such as the exit(), abort(), raise(SIGTERM), and raise(SIGABRT) functions terminate the enclave.
- A PL/I EXIT or STOP statement terminates the enclave.
- Use the callable service IBMHKS to turn hooks on and off. For more information about IBMHKS, see PL/I for MVS & VM Programming Guide.
- C or C++ functions such as exit(), abort(), raise(SIGTERM), and raise(SIGABRT) terminate the entire application as well as the user exit.

CEEBINT is invoked after the enclave has been established, after the Debug Tool initial command string has been processed, and prior to the invocation of compiled code. When invoked, it is passed a parameter list. The parameters are all fullwords and are defined as:

**Number of arguments in parameter list** (input)
- A fullword binary integer
  - On entry: Contains 7
  - On exit: Not applicable

**Return code** (output)
- A fullword binary integer
  - On entry: 0
  - On exit: Able to be set by the exit, but not interrogated by Language Environment

**Reason code** (output)
- A fullword binary integer
  - On entry: 0
  - On exit: Able to be set by the exit, but not interrogated by Language Environment

**Function code** (input)
- A fullword binary integer
  - On entry: 1, indicating the exit is being driven for initialization
  - On exit: Not applicable

**Address of the main program entry point** (input)
- A fullword binary address
  - On entry: The address of the routine that gains control first
  - On exit: Not applicable

**User word** (input/output)
- A fullword binary integer
Run-Time User Exits

- On entry: Value of the user word (CEEAUE_USERWD) as set by the assembler user exit. See page 466 for a description of the (CEEAUE_USERWD) field.
- On exit: The value set by the user exit, maintained by Language Environment and passed to subsequent user exits. It can be accessed from the main() function through the system programming facilities C__xusr() function.

Exit List Address (output)
The address of the exit list control block, Exit_list
- On entry: 0
- On exit: 0, unless you establish a hook exit, in which case you would set this pointer and fill in relevant control blocks. The control blocks for Exit_list and Hook_exit are shown in the following figure.

As supplied, CEEBINT has only one exit defined that you can establish — the hook exit described by the Hook_exit control block. This exit gains control when hooks generated by the PL/I compiler TEST option are executed. You can establish this exit by setting appropriate pointers (A_Exits to Exit_list to Hook_exit).

---

Figure 162. Exit_list and Hook_exit Control Blocks

The control block Exit_list exit contains the following fields:

- **Exit_list_len**
  - The length of the control block; it must be 1

- **Exit_list_hooks**
  - The address of the Hook_exit control block
The control block for the hook exit must contain the following fields:

**Hook_exit_len**
The length of the control block

**Hook_exit_rtn**
The address of a routine you want invoked for the exit. When the routine is invoked, it is passed the address of this control block. Since this routine is invoked only if the address you specify is nonzero, you can turn the exit on and off.

**Hook_exit_fnccode**
The function code with which the exit is invoked. This is always 1.

**Hook_exit_retcode**
The return code set by the exit. You must ensure it conforms to the following specifications:

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Requests that the Debug Tool be invoked next</td>
</tr>
<tr>
<td>4</td>
<td>Requests that the program resume immediately</td>
</tr>
<tr>
<td>16</td>
<td>Requests that the program be terminated</td>
</tr>
</tbody>
</table>

**Hook_exit_rsncode**
The reason code set by the exit. This is always zero.

**Hook_exit_userwd**
The user word passed to the user exits CEEBXITA and CEEBINT

**Hook_exit_ptr**
An exit-specific user word

**Hook_exit_reserved**
Reserved

**Hook_exit_dsa**
The contents of register 13 when the hook was executed

**Hook_exit_addr**
The address of the hook instruction executed
Chapter 29. Assembler Considerations

You can run applications written in assembler language in Language Environment. Applications written in Language Environment-conforming HLLs can also call or be called by assembler language applications. It is important to note that Fortran applications cannot call CEEHDLR or any other Language Environment callable service directly, therefore Fortran condition handling must be done by calling an assembler application to provide condition handling support. Most CEE services can be called from Fortran using AFHCEEN or AFHCEEF, as described in z/OS Language Environment Run-Time Application Migration Guide.

This chapter discusses considerations for assembler applications and introduces library routine retention, a function that can provide performance improvement for applications or subsystems running on z/OS.

You can write assembler language applications that conform to the XPLINK call linkage. The z/OS C/C++ Programming Guide describes how to create XPLINK assembler applications using the EDCXPRLG, EDCXEPLG, and EDCXCALL macros, and describes the XPLINK register conventions, parameter passing conventions and stack layout. z/OS Language Environment Vendor Interfaces has details on the XPLINK architecture that will be useful to an assembler programmer.

Understanding the Basics

Whether you plan to execute a single-language assembler application or a multiple-language application containing assembler code, there are a number of restrictions you must follow under Language Environment.

For example, to communicate with Language Environment and other applications running in the common run-time environment, your assembler application must preserve the use of certain registers and storage areas in a consistent way. Calling conventions for non-XPLINK assembler programs must follow the standard S/370 linkage conventions. Calling conventions for XPLINK assembler programs must follow the XPLINK linkage conventions. In addition, your assembler program is restricted from using some operating system services. These conventions and restrictions are described in this chapter.

Compatibility Considerations

If you are coding a new assembler routine that you want to conform to the Language Environment interface or if your assembler routine calls Language Environment services, you must use the macros provided by Language Environment. For a list of these macros, see “Assembler Macros” on page 483. Throughout this book, Language Environment-conforming assembler routine refers to an assembler routine coded using the CEEENTRY and associated macros.

Control Blocks

Assembler routines that rely on control blocks that were versions of C, COBOL, Fortran, and PL/I (for example, routines that check flags or switches in these control blocks) might not run under Language Environment. These control blocks might have changed. For more information, see one of the migration guides listed in “Bibliography” on page 635.
Assembler Considerations

Save Areas
Any non-XPLINK assembler routine used within the scope of a Language Environment application must use standard S/370 save area conventions. Any XPLINK assembler routine used within the scope of a Language Environment application must use XPLINK save area conventions.

Notes:
1. To call a COBOL program from assembler, set the first two bytes of the save area to hex zero.
2. Language Environment does not support the linkage stack.

CICS
Language Environment-conforming assembler main routines are not supported under CICS.

C and Fortran Duplicate Names
Several external names, shown in column one of Table 61, are identical in C and Fortran. If any of the names is used in an assembler program as an external reference, the C—not the Fortran—entity is obtained. If you wish to obtain the Fortran version, you can instead reassemble using the names shown in column two of Table 61 as a substitute for the C names in column one.

For example, if your assembler program currently references the Fortran ABS function with the instruction:

```
ABSADDR DC V(ABS)
```

you could instead reassemble it with the instruction:

```
ABSADDR DC V(A#ABS)
```

to obtain the Fortran function as before. The C versions of the functions might additionally require a different parameter-list format.

As an alternative to changing the conflicting names in an assembler routine and then reassembling, you can relink the existing routine following the procedure explained in "Resolving Library Module Name Conflicts between Fortran and C" on page 17.

Register Conventions

To communicate properly with assembler routines, you must observe certain register conventions on entry into the assembler routine (while it runs), and on exit from the assembler routine.

Language Environment-conforming assembler and non-Language Environment-conforming assembler each has its own requirements for register conventions when running under Language Environment.

Language Environment-conforming Assembler

When you use the macros listed in “Assembler Macros” on page 483 to write your Language Environment-conforming assembler routines, the macros generate code that follows the required register conventions.

On entry into the Language Environment-conforming non-XPLINK assembler main routine, registers must contain the following values because they are passed without change to the CEEENTRY macro:

R0 Undefined
R1 Address of the parameter list, or zero if no parameters are passed
R13 Caller’s standard register save area
R14 Return address
R15 Entry point address

On entry into the Language Environment-conforming assembler subroutine, these registers must contain the following values when NAB=YES is specified on the CEEENTRY macro:

R0 Reserved
R1 Address of the parameter list, or zero
R12 Common anchor area (CAA) address
R13 Caller’s DSA
R14 Return address
R15 Entry point address
All others Undefined

On entry into a Language Environment-conforming assembler routine, CEEENTRY loads the caller’s registers (R14 through R12) in the DSA provided by the caller. After it allocates a DSA (which sets the NAB field correctly in the new DSA), the first halfword of the DSA is set to hex zero and the backchain is set properly.
Assembler Considerations

At all times while the Language Environment-conforming non-XPLINK assembler routine is running, R13 must point to the routine’s DSA.

At call points, R12 must contain the common anchor area (CAA) address, except in the following cases:
  - When calling a COBOL program
  - When calling an assembler routine that is not Language Environment-conforming
  - When calling a Language Environment-conforming assembler routine that specifies NAB=NO on the CEEENTRY macro

On exit from a Language Environment-conforming assembler routine, these registers contain:
- R0: Undefined
- R1: Undefined
- R14: Undefined
- R15: Undefined
- All others: The contents they had upon entry

Non-Language Environment-conforming Assembler

When you run a non-Language Environment-conforming routine in Language Environment, you must observe the following conventions:
  - R13 must contain the address of the executing routine’s register save area
  - The register save area back chain must be set to a valid 31-bit address (if the address is a 24 bit address, the first byte of the address must be hex zeros)
  - The first two bytes of the register save area must be hex zeros

Considerations for Coding or Running Assembler Routines

This section summarizes some areas you might need to consider when coding or running an assembler routine under Language Environment.

Asynchronous Interrupts

If an asynchronous signal is being delivered to a thread running with POSIX(ON), the thread is interrupted for the signal only when the execution is:
  - In a user C routine, or in a user COBOL routine compiled with the THREAD compiler option
  - Just prior to a return to a C routine or to a return to a user COBOL routine compiled with the THREAD compiler option
  - Just prior to an invocation of a Language Environment library from a user routine

C routines or COBOL routines compiled with the THREAD compiler option may need to protect against asychronous signals based on the application logic including the possible use of the POSIX signal-blocking function that is available.

Condition Handling

Language Environment default condition handling actions occur for assembler routines unless you have registered a user-written condition handler using CEEHDLR (see [z/OS Language Environment Programming Reference](z/OS Language Environment Programming Reference) for more information about CEEHDLR).
Assembler Considerations

Language Environment relinquishes all enclave-level resources that were obtained by Language Environment when the enclave terminates, and all process-level resources when the process terminates.

Access to the Inbound Parameter String
You can access the standardized form of the inbound parameter list for the assembler main routine any time after routine initialization by using one of the following:

- The CEE3PRM (query parameter string) callable service described in [Z/OS Language Environment Programming Reference](https://publib.boulder.ibm.com/infocenter/lnce/v3r1/index.jsp). What CEE3PRM returns depends on the operating system you run under, and the run-time or compiler options you specify. See “What the enclave returns from CEE3PRM” on page 563 for more information.
- The PARMREG output value from the CEEENTRY macro described in “CEEENTRY Macro — Generate a Language Environment-Conforming Prolog” on page 484.

Overlay Programs
Language Environment does not provide explicit support for overlay programs. If programs are overlaid, Language Environment imposes the following restrictions:

- All Language Environment routines and static data must be placed in the root segment.
- All named routines and static data referred to by Language Environment must be in the root segment.
- All ENTRY values or static data addresses passed to any Language Environment service must point to routines in the root segment.
- All routines in the save area chain must be in storage for the whole time that they are in the chain.
- All calls must be inclusive, not exclusive (see your Linkage Editor and Loader User’s Guide for the definitions of these terms).
- Calls that cause a new overlay segment to be loaded must be between two routines in the same language (that is, they cannot be ILC calls).

CEESTART, CEEMAIN, and CEEFMAIN
Assembler programs cannot call or use directly CEESTART, CEEMAIN, or CEEFMAIN as a standard entry point. Results are unpredictable if this rule is violated.

When link-editing an application it must be possible for the link-editor to resolve CEESTART. As long as the NCAL link-editor option is not specified, CEESTART will be automatically resolved. If NCAL is used it becomes necessary to explicitly include CEESTART in the link-edit process.

Mode Considerations
The CEEENTRY macro automatically sets the module to AMODE ANY and RMODE ANY. Therefore, when converting to Language Environment-conforming assembler, if data management macros had been coded using 24-bit mode, they should be changed to use 31-bit addressing mode (see [Z/OS DFSMS Macro Instructions for Data Sets](https://publib.boulder.ibm.com/infocenter/psa/v2r1/index.jsp)). If it is not possible to change all the modules making up the program to use 31-bit addressing mode (and none of the modules are already set to RMODE
Assembler Considerations

24), then it will be necessary to set the module to RMODE 24 during the link-edit process. This is done by specifying the link-edit RMODE option on the invocation PARM or the SETOPT control statement.

Language Environment Library Routine Retention (LRR)

Language Environment library routine retention is a function that provides a performance improvement for those applications or subsystems with the following attributes:

- The application or subsystem invokes programs that require Language Environment.
- The application or subsystem is not Language Environment-conforming. That is, Language Environment is not already initialized when the application or subsystem invokes programs that require Language Environment.
- The application or subsystem, while running under the same task, repeatedly invokes programs that require Language Environment.
- The application or subsystem is not using Language Environment preinitialization services.

Restrictions:

- Language Environment library routine retention is not supported to run on CICS.
- Language Environment library routine retention is not supported to run in an XPLINK environment.
- Language Environment library routine retention is not supported in the z/OS.e environment.

The use of library routine retention does not affect the behavior of applications other than improving their performance.

Language Environment provides a macro called CEELRR, which is used in an assembler program to initialize library routine retention and to terminate library routine retention. See "CEELRR Macro — Initialize/Terminate Language Environment Library Routine Retention" on page 481 for details about the CEELRR macro.

In addition, Language Environment provides two sample programs that use the CEELRR macro:

**CEELRRIN**  This routine uses the CEELRR macro to initialize library routine retention. The source for this routine can be found in member CEELRRIN in SCEESAMP. The load module associated with this routine can be found in SCEERUN with member name CEELRRIN.

**CEELRRTR**  This routine uses the CEELRR macro to terminate library routine retention. The source for this routine can be found in member CEELRRTR in SCEESAMP. The load module associated with this routine can be found in SCEERUN with member name CEELRRTR.

When library routine retention has been initialized, Language Environment keeps a subset of its resources in memory after the environment terminates. As a result, subsequent invocations of programs in the same task that caused Language Environment to be initialized are much faster because the resources can be reused without having to be reacquired and reinitialized.
When library routine retention has been initialized, the resources that Language Environment keeps in memory when it terminates include the following:

- Language Environment run-time load modules
- Language Environment storage associated with the management of the run-time load modules
- Language Environment storage for startup control blocks

When library routine retention is terminated, the resources that Language Environment kept in memory are freed. (Library routines are deleted and storage is freed.)

**Note:** If library routine retention is initialized, and the task in which it is being used is terminated, the operating system frees the Language Environment resources as part of task termination.

### Using Library Routine Retention

If you are going to use library routine retention, you need to be aware of the following:

- Library routine retention cannot be used on CICS.
- To successfully initialize library routine retention or terminate library routine retention, Language Environment must not be currently initialized.

For example, if you use CEELRR with ACTION=INIT in a Language Environment-conforming assembler program, library routine retention is not initialized, because the invocation of the assembler program caused Language Environment to be initialized.

### Library Routine Retention and Preinitialization

The Language Environment preinitialization services can be used while library routine retention is initialized. However, the Language Environment resources initialized and terminated with Language Environment preinitialization services are not kept in memory when library routine retention is initialized. There is no sharing of resources between Language Environment when initialized with preinitialization services and an environment initialized by invoking an HLL program without using preinitialization services. There is no performance benefit of library routine retention for those applications and subsystems that bring up a Language Environment preinitialized environment, and then use the preinitialization services to invoke programs that require Language Environment.

### CEELRR Macro — Initialize/Terminate Language Environment Library Routine Retention

CEELRR is used to tell Language Environment to initialize and terminate library routine retention. The macro generates reentrant code.

#### Syntax

```
<label> CEELRR ACTION=INIT/TERM
```

*label*

Assembler label on this macro generation.
Assembler Considerations

ACTION=
The action to be performed by Language Environment with regard to library routine retention. Valid values are INIT and TERM. A value of INIT tells Language Environment to initialize library routine retention. A value of TERM tells Language Environment to terminate library routine retention. You must specify the ACTION value.

Usage Notes:
1. The macro must be used in an assembler routine that is not Language Environment-conforming.
2. The contents of the following registers are destroyed by the macro invocation:
   - R14
   - R15: Upon return, contains the return code
   - R0
   - R1
3. The code generated by the macro expansion assumes that R13 has a standard RSA available.
4. One of the following return codes is put in R15 upon completion of the code generated by the CEELRR macro with ACTION=INIT:
   - 0 Library routine retention was successfully initialized.
   - 4 Library routine retention is already initialized. No action was taken.
   - 8 Library routine retention was not initialized; the parameter list is not recognized.
   - 12 Library routine retention was not initialized due to one of the following problems:
     - There was insufficient storage.
     - There was an error in an attempt to load CEEBINIT or CEEBLIBM.
   - 16 Library routine retention was not initialized because Language Environment is currently initialized.
     This return code can occur in the following example scenarios:
     - A program that is running with Language Environment calls an assembler program that uses CEELRR with ACTION=INIT.
     - An assembler program calls IGZERRE to initialize a reusable environment, and then it uses CEELRR with ACTION=INIT.
     - A reusable environment is established with the RTEREUS run-time option and a call is made to an assembler program that uses CEELRR with ACTION=INIT.
   - 20 Library routine retention was not initialized because the Language Environment preinitialized environment has been established and is dormant.
     This return code can occur in the following example scenarios:
     - An assembler program calls CEEPIPI to preinitialize Language Environment, and then it uses CEELRR with ACTION=INIT.
     - An assembler program uses the PL/I preinitialize program interface, and then it uses CEELRR with ACTION=INIT.
   - 44 LRR is not supported in the z/OS.e environment.
5. One of the following return codes is put in R15 upon completion of the code generated by the CEELRR macro with ACTION=TERM:
Assembler Considerations

0  Library routine retention was successfully terminated. All resources associated with library routine retention were freed.
4  Library routine retention is not initialized. No action was taken.
8  Library routine retention was not terminated; the parameter list is not recognized.
16 Library routine retention was not terminated because Language Environment is currently initialized. This return code can occur in the following example scenarios:
   • A program that is running with Language Environment calls an assembler program that uses CEELRR with ACTION=TERM.
   • An assembler program calls IGZERRE with the initialize function, and then it uses CEELRR with ACTION=TERM.
   • A reusable environment is established with the RTEREUS run-time option and a call is made to an assembler program that uses CEELRR with ACTION=TERM.
20 Library routine retention was not terminated because the Language Environment preinitialized environment has been established and is dormant.

   This return code can occur in the following example scenarios:
   • An assembler program calls CEELRR to preinitialize Language Environment, and then it uses CEELRR with ACTION=TERM.
   • An assembler program uses the PL/I preinitialize program interface, and then it uses CEELRR with ACTION=TERM.

Assembler Macros

Language Environment provides the following macros to assist in the entry and exit of assembler routines, to map the CAA and DSA, to generate the appropriate fields in the program prolog area (PPA), to create assembler DLLs, and to use DLLs from assembler routines:

   • CEEENTRY generates a Language Environment-conforming prolog. You must use CEEENTRY in conjunction with the following macros, except for CEELOAD (see page 484 for syntax).
   • CEETERM generates a Language Environment-conforming epilog and terminates the assembler routine (see page 487 for syntax).
   • CEECAA generates a CAA mapping (see page 488 for syntax).
   • CEEDSA generates a DSA mapping (see page 489 for syntax).
   • CEEPFA generates the appropriate fields in the PPA in your assembler routine. The fields describe the entry point of a Language Environment block (see page 489 for syntax).
   • CEELOAD loads a Language Environment-conforming assembler routine; the target of CEELOAD must be a subroutine (see page 491 for syntax).
   • CEEFETCH dynamically loads a Language Environment-conforming routine; the target of CEEFETCH must be a subroutine (see page 494 for syntax).
   • CEERELES dynamically deletes a Language Environment-conforming routine (see page 498 for syntax).
   • CEECALL calls a Language Environment-conforming routine. It is similar to the CALL macro, except that it supports dynamic calls to routines in a DLL (see page 499 for syntax).
Assembler Considerations

- CEEPDDA defines a data item in WSA, or declares a reference to an imported data item (see page 501 for syntax).
- CEEPLDA returns the address of a data item defined by CEEPDDA. It is intended to be used to get the address of imported or exported variables residing in the Writeable Static Area (WSA) (see page 503 for syntax).

For a description of Assembler macros to assist in writing XPLINK assembler routines, see z/OS C/C++ Programming Guide.

CEEENTRY Macro — Generate a Language Environment-Conforming Prolog

CEEENTRY provides a Language Environment-conforming prolog. Code is generated in cooperation with the CEEPPA macro (see CEEPPA Macro — Generate a PPA on page 489 for syntax). The macro generates reentrant code.

You must use CEEENTRY in conjunction with the macros CEETERM, CEECAA, CEEDSA, and CEEPPA.

CEEENTRY assumes that the registers contain what is described in Register Conventions on page 477 for assembler main routines.

To call an assembler routine from an existing Fortran program, or to make a static call from OS/VS COBOL or VS COBOL II, CEEENTRY must specify NAB=NO and MAIN=NO.

Syntax

```
  name CEEENTRY PPA=label, AUTO=value,

  NAB=YES, MAIN=YES, ENCLAVE=YES,

  EXECOPS=YES, PARMREG=register,

  EXPORT=YES, BASE=register

  HOST=MVS, TSO, CICS, IMS, OS

name The entry name (and the CSECT name, if this is the first call to CEEENTRY).
```
Assembler Considerations

PPA=
The label of the corresponding PPA (Program Prolog Area) generated using the CEEPAA macro. If unspecified, the name "PPA" is used.

AUTO=
The total number of bytes (rounded up to a double word) used by prolog code for the DSA and local automatic variables that are to be allocated for the duration of this routine. If unspecified, the default is only the size of the DSA without any automatic variables. This default size is indicated by the label CEEDSASZ.

CEEDSASZ (the DSA mapping generated by the CEEDSA macro. See CEEDSA Macro — Generate a DSA Mapping on page 489 in topic 5.2.5.4 for syntax).

NAB=

YES
Indicates that the previous save area has a NAB (next available byte) value; YES is the default. In general,

- If your routine is always called by a Language Environment-conforming assembler routine, specify NAB=YES.
- If your routine can be called by a non-Language Environment-conforming assembler routine, specify NAB=NO.

NO
Indicates that the previous save area may not contain the NAB. Code to find the NAB is generated. This parameter is ignored if MAIN=YES is specified. You must specify MAIN=NO and NAB=NO to call an assembler routine from an existing Fortran application, or to make a static call from OS/VS COBOL or VS COBOL II.

MAIN=

YES
Indicates that the Language Environment environment should be brought up. Designates this assembler routine as the main routine in the enclave. YES is the default. If you specify MAIN=YES, you cannot specify register 2 as the base register for the module. MAIN=YES is not supported under CICS.

The following is accomplished by the macro invocation:

- The caller’s registers (14 through 12) are saved in a DSA provided by the caller.
- The base register is set (see BASE= for more information).
- Register 12 is set with an address of CEECAA.
- Register 13 is set with an address of CEEDSA.
- PARMREG (Register 1 is the default) is set based on PLIST.
- All other registers are undefined.

NO
Designates this assembler routine as a subroutine in the enclave. NO should be specified when the Language Environment environment is already active and only prolog code is needed. You must specify NAB=NO in order to call an assembler routine from an existing Fortran application, or to make a static call from OS/VS COBOL or VS COBOL II.
Assembler Considerations

The following is accomplished by the macro invocation:

- The caller’s registers (14 through 12) are saved in a DSA provided by the caller.
- The base register is set (see BASE= for more information).
- Register 13 is set with an address of CEEDSA.
- PARMREG is set (see PARMREG.)
- All other registers are undefined.

ENCLAVE=

Yes
Indicates that Language Environment should always create a nested enclave for this program.

ENCLAVE=YES may only be specified when MAIN=YES.
The use of ENCLAVE=YES will result in increased storage and CPU usage. Most applications will not need a new enclave; therefore ENCLAVE=NO should be used.

No
Indicates that a new enclave is not needed for this program.
If you do not specify a value, NO is assumed.

EXECOPS=

Yes
Indicates that the main routines are to honor run-time options on the inbound parameter string. This option is applicable only when MAIN=YES is in effect for the routine. The EXECOPS setting is ignored if MAIN=NO is specified.

If you do not specify a value, YES is assumed.

No
Indicates that there are no run-time options in the inbound parameter string. Language Environment considers the entire inbound parameter string as program arguments, but does not attempt to process run-time options and remove them from the inbound parameter string.

PARMREG=
Specifies the register to hold the inbound parameters. If you do not specify a value, register 1 is assumed.
For MAIN=YES, the value in the PARMREG is determined by PLIST. For MAIN=NO and PARMREG=1 (PARMREG defaults to 1), register 1 is restored from the save area passed to the routine. When MAIN=NO and PARMREG is not equal to 1, register 1 is used to load the specified PARMREG. Then, register 1 is used for the CEEENTRY expansion.

Export=
Indicates whether this entry point will be exported.

No
This entry point can only be called from other routines that are link-edited into the same program object.

Yes
This entry point will be marked as an exported DLL function. If you specify EXPORT=YES, then you must use the GOFF assembler option.
If you want the exported name to be a long name and/or mixed case, follow the CEEENTRY macro with an ALIAS statement. For more details on DLLs, including full sample assembler DLL routines, see Chapter 4, “Building and Using Dynamic Link Libraries (DLLs),” on page 43.

For the entry point to be available as an exported DLL function, you must specify the DYNAM(DLL) binder option, and the resulting program object must reside in a PDSE.

**BASE=** Establishes the register(s) that you specify here as the base register(s) for this module. If you do not specify a value, register 11 is assumed; register 12 cannot be used. Also, if you specify MAIN=YES, you cannot specify register 2 as the base register for the module. When more than one register is specified, the registers must be separated by commas and enclosed in parentheses. The same register cannot be specified more than once.

**PLIST=** Indicates that the main routines are to honor PLIST format on the inbound parameter string. This option is applicable only when MAIN=YES is in effect for the routine. The PLIST settings are ignored if MAIN=NO is specified. If you do not specify a value, HOST format is assumed.

The HOST format will set the specified PARMREG based on the environment in which the program is executing. For example, in an environment that assumes CEEENTRY defaults, register 1 is set equal to the address of a one word PLIST that contains the address of a field with a halfword-prefixed string of user parameters. To obtain the inbound parameter list as specified, use PLIST (OS).

**Usage Notes:**

1. The CEEENTRY macro automatically sets the module to AMODE ANY and RMODE ANY. Therefore, when converting to Language Environment-conforming assembler, if data management macros had been coded using 24-bit mode, they should be changed to use 31-bit addressing mode (see [z/OS DFSMS](https://www.ibm.com/support/knowledgecenter/en/SSLTBK_3749/zos/zosdfsms/)), If it is not possible to change all the modules making up the program to use 31-bit addressing mode (and none of the modules are already set to RMODE 24), then it will be necessary to set the module to RMODE 24 during the link-edit process. This is done by specifying the link-edit RMODE option on the invocation PARM or the SETOPT control statement.

2. Unless otherwise indicated, no register values should be expected to remain unchanged after the code generated by CEEENTRY has executed.

3. When more than one CEEENTRY macro invocation occurs in an assembly, it is the programmer’s responsibility to code DROP statements for the base registers set up by the previous invocation of the CEEENTRY macro.

**CEETERM Macro — Terminate a Language Environment-Conforming Routine**

CEETERM provides a Language Environment-conforming epilog and is used to terminate, or return from, a Language Environment-conforming routine. If used with a main entry, the appropriate call is made to Language Environment termination routines.
Syntax

```plaintext
name—CEETERM—RC=return_code—MODIFIER=modifier—MF=L(E,ctrl_addr)
```

**name**
The entry name (and the CSECT name, if this is for a main entry).

**RC=**
The *return code* that is to be placed into R15 after the *MODIFIER* is added to it, if terminating a main routine. If returning from a Language Environment subroutine, the return code itself is placed into R15, without *MODIFIER* being added to it. *return code* can be a fixed constant, variable, or register 2–12.

**MODIFIER=**
The return code *modifier* that is multiplied by the appropriate value (based upon the operating system), added to the return code, and placed into R15 (if terminating a main routine). The MODIFIER is independently placed into R0. Modifier can be a fixed constant, variable, or register 2–12.

**MF=L**
Indicates the list form of the macro. A remote control program parameter list for the macro is defined, but the service is not invoked. The list form of the macro is usually used in conjunction with the execute form of macro.

**MF=(E,ctrl_addr)**
Indicates the execute form of the macro. The service is invoked using the remote control program parameter list addressed by *ctrl_addr* (normally defined by the list form of the macro, it cannot be register 0).

**Usage Notes:**
1. The MF=L and the MF=(E, *ctrl_addr*) parameters cannot both be coded for the same macro invocation. If neither is coded, the immediate form of the macro is used. The immediate form generates an inline parameter list, and generates nonreentrant code.
2. The address of the name can be specified as a register using parentheses ().
3. The macro invocation destroys the registers R1, R14, and R15.
4. MF=L and MF=(E, *ctrl_addr*) can only be used when CEEENTRY MAIN=YES has been specified. These parameters are not necessary when CEEENTRY MAIN=NO has been specified; in that environment, CEETERM automatically generates reentrant code.

**CEECAA Macro — Generate a CAA Mapping**

```
  Syntax

  CEECAA
```
CEECAA is used to generate a common anchor area (CAA) mapping. This macro has no parameters, and no label can be specified. CEECAA is required for the CEEENTRY macro.

**CEEDSA Macro — Generate a DSA Mapping**

Syntax

```
CEEDSA
```

CEEDSA is used to generate a dynamic save area (DSA) mapping. This macro has no parameters, and no label can be specified. The minimum size of the DSA is contained in an assembler EQUATE CEEDSASZ. CEEDSA is required for the CEEENTRY macro.

**CEEPPA Macro — Generate a PPA**

CEEDPPA is used to generate the Language Environment program prolog area (PPA). The PPA defines constants that describe the entry point of a Language Environment block. It is generated at the time of assembly; one PPA is generated per entry point. The CEEPPA macro is required for the CEEENTRY macro.

Syntax

```
label CEEPPA
LIBRARY=YES, NO
PPA2=YES, NO
EXTPROC=YES, NO
TSTAMP=YES, NO
PEP=YES, NO
INSTOP=YES, NO
EXITDSA=YES, NO
OWNEXM=YES, NO
EPNAME=name
VER=version_number
REL=release_number
MOD=level
DSA=YES, NO
```

*label* The name of the PPA. If you specified a name for **PPA** in the CEEENTRY macro, you must specify the same name here. If you did not specify a name for **PPA** in the CEEENTRY macro, you must specify “**PPA**” (the CEEENTRY default PPA label) as the name here.
**Assembler Considerations**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>LIBRARY=</strong></td>
<td>Indicates whether the routine is a Language Environment library routine. Valid values for LIBRARY are <strong>YES</strong> and <strong>NO</strong>. If you do not specify a value, <strong>NO</strong> is used. Use of this IBM-supplied default is recommended.</td>
</tr>
<tr>
<td><strong>PPA2=</strong></td>
<td>Instructs the macro to generate a PPA2 or suppress the generation of the PPA2. A PPA2 is a program prolog area that defines constants for the CSECT. Only one is used, independent of the number of entry points. Valid values for PPA2 are <strong>YES</strong> and <strong>NO</strong>. If you do not specify a value, <strong>YES</strong> is used, which generates a PPA2 field.</td>
</tr>
<tr>
<td><strong>EXTPROC=</strong></td>
<td>Indicates if this routine is an external procedure or an internal procedure. An internal procedure is known only within the CSECT and can be called only from within the CSECT. Valid values for EXTPROC are <strong>YES</strong> and <strong>NO</strong>. If you do not specify a value, <strong>YES</strong> is used, which indicates that the block is an external procedure.</td>
</tr>
<tr>
<td><strong>TSTAMP=</strong></td>
<td>Indicates whether a timestamp, indicating the date and time of assembly, should be generated. Valid values for TSTAMP are <strong>YES</strong> and <strong>NO</strong>. If you do not specify a value, <strong>YES</strong> is used and a timestamp is generated.</td>
</tr>
<tr>
<td><strong>PEP=</strong></td>
<td>Indicates if this entry point is primary or secondary. A secondary entry point is an alternate entry point. Some Language Environment facilities, such as CEE3DMP, report information based on the primary entry point only. Valid values for PEP are <strong>YES</strong> and <strong>NO</strong>. If you do not specify a value, <strong>YES</strong> is used, which indicates that this is a primary entry point (PEP).</td>
</tr>
<tr>
<td><strong>INSTOP=</strong></td>
<td>Indicates if time spent in this routine should be attributed to the program (rather than to the “system”). Valid values for INSTOP are <strong>YES</strong> and <strong>NO</strong>. If you do not specify a value, <strong>NO</strong> is used, which indicates that time should be attributed to the system. The information is intended to be used by application performance analysis tools.</td>
</tr>
<tr>
<td><strong>EXITDSA=</strong></td>
<td>Indicates whether the code should gain control on GOTO out of block. Valid values for EXITDSA are <strong>YES</strong> and <strong>NO</strong>. If you do not specify a value, <strong>NO</strong> is used, which indicates that the code does not gain control for GOTO out of block. Use of this IBM-supplied default is recommended.</td>
</tr>
<tr>
<td><strong>OWNEXM=</strong></td>
<td>Specifies if this routine should participate in condition handling according to the exception model of its own member language (OWNEXM=<strong>YES</strong>), or according to the exception model inherited from the caller’s member language (OWNEXM=<strong>NO</strong>). Valid values for OWNEXM are <strong>YES</strong> and <strong>NO</strong>. If you do not specify a value, <strong>YES</strong> is used. Use of this IBM-supplied default is recommended.</td>
</tr>
<tr>
<td><strong>EPNAME=</strong></td>
<td>Indicates the entry point name. If you do not specify a value, the name of the CSECT is used.</td>
</tr>
<tr>
<td><strong>VER=</strong></td>
<td>The <em>version number</em> for the routine. This field is not interrogated by Language Environment. Valid values for VER are 1 through 99. If you do not specify a value, 1 is used.</td>
</tr>
</tbody>
</table>
**REL=** The *release number* for the routine. This field is not interrogated by Language Environment. Valid values for REL are 1 through 99. If you do not specify a value, 1 is used.

**MOD=** The modification *level* for the routine. This field is not interrogated by Language Environment. Valid values for MOD are 1 through 99. If you do not specify a value, 0 is used.

**DSA=YES** Indicates whether this procedure has a DSA. Valid values for DSA are YES and NO. If you do not specify a value, YES is used, indicating that the code has an associated DSA. Use of this IBM-supplied default is recommended.

**CEELOAD Macro — Dynamically Load a Language Environment-Conforming Routine**

CEELOAD is used to dynamically load a Language Environment-conforming routine. It does not create a nested enclave, so the target of CEELOAD must be a subroutine.

There is no corresponding service to delete Language Environment-conforming routines. You should not use system services to delete modules that you load using CEELOAD; during thread (if SCOPE=THREAD) or enclave (if SCOPE=ENCLAVE) termination, Language Environment deletes modules loaded by CEELOAD.

Using CEELOAD imposes restrictions on further dynamic loading or dynamic calls or fetches; results are unpredictable if these rules are violated.

- You cannot dynamically load a routine with CEELOAD that has already been dynamically loaded by CEELOAD or has been fetched or dynamically called.
- You cannot fetch or dynamically call a routine that has already been dynamically loaded by CEELOAD.

If CEELOAD completes successfully, the address of the loaded routine is found in R15. You can then invoke the routine using BALR 14,15 (or BASSM 14,15).

Language Environment returns the address of the target routine with the high-order bit indicating the addressing mode (AMODE) of the routine. Language Environment-enabled programs return in the AMODE in which they are entered. Because Language Environment does not provide any AMODE switching on behalf of the target routine, you must provide any necessary AMODE switching code.

The macro invocation destroys the following registers:

- R0
- R1
- R14
- R15 (upon return, contains the target address)

When the macro code is expanded and run, the following assumptions are made:

- R12 points to the CAA.
- R13 has a standard Language Environment DSA available.
The assembler label you give to this invocation of the macro. A label is required if MF=L; otherwise it is optional.

**NAME=**
The name of the entry point to be loaded by Language Environment. If MF=I or MF=L, you must specify either NAME or NAMEADDR, but not both.

**NAMEADDR=**
The address of a halfword-prefixed name that should be loaded by Language Environment. This can be an A-type address or a register (register 2 through 11). If MF=I or MF=L, you must specify either NAME or NAMEADDR, but not both.

The address of the name can be specified as a register using parentheses ()

**SCOPE=THREAD**
Indicates that the load is to be scoped to the thread level. Modules loaded at the thread level are deleted automatically at thread termination.

**SCOPE=ENCLAVE**
Indicates that the load is to be scoped to the enclave level. Modules loaded at the enclave level are deleted automatically at enclave termination.

**SCOPE=ENCLAVE**
is the default.

**FEEDBACK=**
The name of a variable to contain the resulting 12-byte feedback token. If you omit this parameter, any nonzero feedback token that results is signaled.

The following symbolic conditions might be returned from this service:

<table>
<thead>
<tr>
<th>Symbolic Feed-back Code</th>

</tr>
</tbody>
</table>

**MF=I**

Indicates the immediate form of the macro. The immediate form generates an inline parameter list, and generates nonreentrant code.

**MF=L**

Indicates the list form of the macro. A remote control program parameter list for the macro is defined, but the service is not invoked. The list form of the macro is usually used in conjunction with the execute form of the macro.

**MF=(E, ctrl_addr)**

Indicates the execute form of the macro. The service is invoked using the remote control program parameter list addressed by `ctrl_addr` (normally defined by the list form of the macro).

Only one of the MF=I, MF=L, or MF=(E, `ctrl_addr`) parameters can be coded for the same macro invocation. If none is coded, the immediate form of the macro is used.

The following example illustrates an invocation of the CEELOAD Macro.

**Example:**

```
CLOADTST CEEENTRY PPA=LEPPA,AUTO=DSALGTH
********************************************************
* Copy parameters to be passed to CEELOAD
********************************************************
MVC LOADPL(PLLEN),PLLIST
********************************************************
* Invoke CEELOAD to load module HIWORLD
********************************************************
CEELOAD MF=(E,LOADPL) LOAD ROUTINE
********************************************************
* Pass control to HIWORLD
********************************************************
BALR 14,15 INVOKE ROUTINE
********************************************************
* Invoke CEETERM to return to Caller
********************************************************
CEETERM RC=(15),MF=(E,DSARPL) BACK TO CALLER
********************************************************
* Constants
********************************************************
PLLIST CEELOAD MF=l,NAME=HIWORLD,SCOPE=THREAD
PLLEN EQU *-PLLIST
LEPPA CEEPPA ,
********************************************************
* Mappings
********************************************************
```
Assembler Considerations

**Usage Notes:**

1. Language Environment issues the appropriate load command according to the Language Environment search order (described in "Program Library Definition and Search Order" on page 81) and performs the necessary dynamic updates to accommodate the new load module.

2. Language Environment performs any language-related initialization required.

3. You cannot use CEEDSA to load a program object which was created using the program management binder. You can, however, use CEEFETCH for loading program objects.

4. You cannot use CEEDSA to load C++ modules, because C++ modules are always compiled RENT and have writable static that is not switched when control passes between functions.

5. #pragma linkage (xxx, fetchable) should not be used. If a module is linked with #pragma linkage (xxx, fetchable), it will have CEESTART as an entry point, which is not allowed, and the module could have writable static requirements that would not be handled using CEEDSA.

   When using CEEDSA to load a C module, the function or functions within this module must not be designated as fetchable. The #pragma linkage (xxx, fetchable) directive should not be coded in the module. Instead, such modules should be fetched using the fetch() function.

6. #pragma linkage (xxx, COBOL) should not be used.

7. For C users, the load module entry point must be the function name, and cannot be CEESTART (nested environment initialization causes Language Environment to abend). You cannot use CEEDSA to load any function that uses writable static. The module must be built NORENT and the entry point must be a C function, not CEESTART.

8. The CEEPPA macro must be used once per entry point. The macro therefore uses a 3 digit index value to generate unique names for each macro expansion. This index will limit the total number of entry points a single assembler source may contain.

**CEEFETCH Macro — Dynamically Load a Language Environment-Conforming Routine**

CEEFETCH is used to dynamically load a Language Environment-conforming routine. Because it does not create a nested enclave, the target of CEEFETCH must be a subroutine.

**Restriction:** CEEFETCH only works with C/C++ and COBOL.

Use the CEERELES macro to delete routines loaded with CEEFETCH. You should not use system services to delete modules that you load using CEEFETCH; during thread (if SCOPE=THREAD) or enclave (if SCOPE=ENCLAVE) termination, Language Environment deletes modules loaded by CEEFETCH.
Restriction: CEERELES only works with C/C++ and COBOL.

If CEEFETCH completes successfully, the address of the target routine is found in R15. You can then invoke the routine using the BALR 14,15 (or BASSM 14,15) instruction.

Language Environment returns the address of the target routine with the high-order bit indicating the addressing mode (AMODE) of the routine. Language Environment-enabled programs return in the AMODE in which they are entered. Because Language Environment does not provide any AMODE switching on behalf of the target routine, you must provide any necessary AMODE switching code.

For example:

```
LA 2,RESET SAVE BRANCH ADDRESS AND CURRENT
BSM 2,0 AMODE IN REGISTER 2
BASSM 14,15 CALL COBOL PROGRAM
BSM 0,2 BRANCH AND RESTORE AMODE FROM REG. 2
RESET DS OH
```

The macro invocation destroys the following registers:
- R0
- R1
- R14
- R15 (upon return, contains the target address)

When the macro code is expanded and run, the following assumptions are made:
- R12 points to the CAA.
- R13 has a standard Language Environment DSA available.

Syntax

```
label—CEEFETCH—NAME=—name—NAMEADDR=—nameaddr—,
SCOPE=ENCLAVE,
SCOPE=THREAD,
SEARCH=MVS,
SEARCH=HFS,
SEARCH=MVSHFS,
SEARCH=HFSMVS,
TOKEN=—token—,
FEEDBACK=—fbcode—,
MF=I,
MF=L,
MF=(E,ctrl_addr)
```

`label` The assembler label you give to this invocation of the macro. A label is required if MF=L is specified; otherwise, it is optional.
Assembler Considerations

NAME=name

The name of the entry point to be loaded by Language Environment. The maximum length of name is eight characters. If a longer name is needed, the NAMEADDR parameter must be used. You cannot specify NAME and NAMEADDR together.

NAMEADDR=nameaddr

The address of a halfword-prefixed name that should be loaded by Language Environment. A halfword prefix name is a string where the first two bytes identify the length of a name string and are followed by the name string itself. This can be an A-type address or a register (register 2 through 11). The address of the name can be specified as a register using parentheses (). The maximum length of the name is 1023 characters. You cannot specify NAME and NAMEADDR together.

SCOPE=THREAD

Indicates that the load is to be scoped to the thread level. Modules loaded at the thread level are deleted automatically at thread termination.

SCOPE=ENCLAVE

Indicates that the load is to be scoped to the enclave level. Modules loaded at the enclave level are deleted automatically at enclave termination; this is the default.

TOKEN=token

The name of a variable to contain the resulting 4-byte token. This variable must be passed to the CEERELES macro if the load module is to be deleted. If MF=I or MF=L are specified, you must specify TOKEN.

SEARCH=MVS

Indicates that only the MVS file system is to be searched for the load module; this is the default.

SEARCH=HFS

Indicates that only the HFS file system is to be searched for the load module.

SEARCH=MVSHFS

Indicates that the MVS file system is to be searched first and then the HFS file system for the load module.

SEARCH=HFSMVS

Indicates that the HFS file system is to be searched first and then the MVS file system for the load module.

FEEDBACK=fbcode

The name of a variable to contain the resulting 12-byte feedback token. If you omit this parameter, any nonzero feedback token that results is signaled. The following symbolic conditions might be returned from this service:

<table>
<thead>
<tr>
<th>Symbolic Feedback Code</th>
<th>Severity</th>
<th>Message Number</th>
<th>Message Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>

<td>The module or language list is not supported in this environment.</td>
</tr>
</tbody>
</table>

**MF=I**
- Indicates the immediate form of the macro. The immediate form generates an inline parameter list and generates nonreentrant code. This is the default value.

**MF=L**
- Indicates the list form of the macro. A remote control program parameter list for the macro is defined, but the service is not invoked. The list form of the macro is usually used in conjunction with the execute form of the macro.

**MF=(E, ctrl_addr)**
- Indicates the execute form of the macro. The service is invoked using the remote control program parameter list addressed by `ctrl_addr` (usually defined by the list form of the macro).

- Only one of the MF=I, MF=L, or MF=(E, `ctrl_addr`) parameters can be coded for the same macro invocation. If none is coded, the immediate form of the macro is used.

**Usage Notes:**

1. Language Environment issues the appropriate load command according to Language Environment search order (described in "Program Library Definition and Search Order" on page 81), and performs the necessary dynamic updates to accommodate the load module.

2. Language Environment performs any language-related initialization required.

3. Any COBOL, PL/I, or Fortran module that will be fetched, dynamically called, or CEEFETCHed more than once must be reentrant.

4. When using CEEFETCH to fetch a C module, the C module must contain `#pragma linkage (xxx, fetchable)`. For exceptions to this rule, see the fetch() information in "z/OS C/C++ Run-Time Library Reference".

5. CEEFETCH can be used in a non-XPLINK Assembler program to fetch an XPLINK-compiled module. The fetched XPLINK-compiled module must contain `#pragma linkage(xxx, fetchable)`. The address of the target routine returned by CEEFETCH in R15 contains any necessary glue code to call an XPLINK routine from non-XPLINK, and can still be invoked using BALR 14,15. All rules and restrictions on the environment imposed by XPLINK still apply. See Chapter 3, "Using Extra Performance Linkage (XPLINK)," on page 29.
CEERELES Macro — Dynamically Delete a Language Environment-Conforming Routine

CEERELES is used to dynamically delete a Language Environment-conforming routine. The macro invocation destroys the following registers:

- R0
- R1
- R14
- R15

When the macro code is expanded and run, the following assumptions are made:

- R12 points to the CAA.
- R13 has a standard Language Environment DSA available.

Syntax

```
label--CEERELES TOKEN=token, FEEDBACK=fbcode,
```

**label**

The assembler label you give to this invocation of the macro. A label is required if MF=L is specified; otherwise, it is optional.

**TOKEN=token**

The name of a variable that contains the token returned by the CEEFETCH macro. If MF=I or MF=L, you must specify TOKEN.

**FEEDBACK=fbcode**

The name of a variable to contain the resulting 12-byte feedback token. If you omit this parameter, any nonzero feedback token that results is signaled. The following symbolic conditions might be returned from this service:

<table>
<thead>
<tr>
<th>Symbolic Feedback Code</th>
<th>Severity</th>
<th>Message Number</th>
<th>Message Text</th>
</tr>
</thead>
<tbody>
<tr>
<td>CEE000</td>
<td>0</td>
<td>—</td>
<td>The service completed successfully.</td>
</tr>
<tr>
<td>CEE38N</td>
<td>3</td>
<td>3351</td>
<td>An event handler was unable to process a request successfully.</td>
</tr>
<tr>
<td>CEE39K</td>
<td>1</td>
<td>3380</td>
<td>The target load module was not recognized by Language Environment.</td>
</tr>
<tr>
<td>CEE3DG</td>
<td>3</td>
<td>3504</td>
<td>Delete service request for <em>module-name</em> was unsuccessful.</td>
</tr>
<tr>
<td>CEE3E0</td>
<td>3</td>
<td>3520</td>
<td>The token passed to the CEERELES macro was invalid.</td>
</tr>
</tbody>
</table>
MF=I
Indicates the immediate form of the macro. The immediate form generates an inline parameter list, and generates nonreentrant code.

MF=L
Indicates the list form of the macro. A remote control program parameter list for the macro is defined, but the service is not invoked. The list form of the macro is usually used with the execute form of the macro.

MF=(E,ctrl_addr)
Indicates the execute form of the macro. The service is invoked using the remote control program parameter list addressed by ctrl_addr (usually defined by the list form of the macro).

Only one of the MF=I, MF=L, or MF=(E, ctrl_addr) parameters can be coded for the same macro invocation. If none is coded, the immediate form of the macro is used.

Usage Notes:
1. Language Environment issues the appropriate operating system delete command and performs the necessary dynamic updates to accommodate the deleted load module.
2. Language Environment performs any language-related cleanup required.

**CEEPCALL Macro — Call a Language Environment-Conforming Routine**

The CEEPCALL macro passes control to a control section at a specified entry point. The target of CEEPCALL can be resolved either statically (link-edited with the same program object) or dynamically (imported from a DLL). The only required positional parameter is the name of the called entry point. This name is case sensitive, and can be up to 255 characters in length. The optional parameter list will be pointed to by General Purpose Register (GPR) 1.

Since only REENTRANT Assembler code is supported by this macro, it must be specified as a combination of LIST and EXECUTE forms so that the parameter list can be built in automatic (ie. stack) storage.

The CEEPCALL macro does not generate any return codes. A return code may be placed in GPR 15 by the called program.

GPRs 1, 14, and 15 are not preserved by this macro.

**Syntax**

```
CEEPCALL label, (parm1, ...) ,VL , MF=L
```

or

```
CEEPCALL label, (parm1, ...) ,MF=L
```
Assembler Considerations

Syntax

```
CEEPCALL entry-name [ (parm1, ... ) ], MF=(E, prob_addr)
```

*label*
Optional symbol beginning in column 1.

*entry-name*
Specifies the entry name of the program to be given control. This entry name can reside in the same program object, or can be an exported DLL function.

*(parm1, ...)*
One or more optional parameter(s) to be passed to the called program, separated by commas. In the list form, these are specified as A-type addresses, and in the execute form are RX-type addresses or specified as registers (2) - (12).

To create the parameter list, the calling program creates a list of addresses of each parameter in the order designated. In the execute form of the macro, GPR 1 contains the address of the parameter list when the program receives control. (If no parameters are coded, GPR 1 is not altered.) See Figure 164 on page 501.

*VL*
Code VL only if the called program can be passed a variable number of parameters. VL causes the high-order bit of the last address parameter to be set to 1; the bit can be checked to find the end of the list.

*MFL*
Creates the list form of the CEEPCALL macro to construct a nonexecutable problem program parameter list. This list form generates only ADCONs of the address parameters. You should refer to this problem program parameter list in the execute form of a CEEPCALL macro.

*MFE=(E,prob_addr)*
Creates the execute form of the CEEPCALL macro which can refer to and modify a remote problem program parameter list. Only executable instructions and a function descriptor representing the entry point are generated.

Usage Notes:
1. This macro requires the G0FF Assembler option
2. This macro requires the binder to link-edit, and the RENT and DYNAM(DLL) binder options. You will also need the CASE(MIXED) binder option if the entry-name is mixed case.
3. The output from the binder must be a PM3 (or higher) format program object, and therefore must reside in either a PDSE or a UNIX file system.

For more details on DLLs, including full sample assembler DLL routines, see Chapter 4, “Building and Using Dynamic Link Libraries (DLLs),” on page 43. The following example illustrates an invocation of the CEEPCALL Macro to call the routine named Bif1 with no parameters:
Assembler Considerations

Figure 163. Example calling routine named Bif5 with no parameters:

The following example illustrates an invocation of the CEEPCALL Macro to call the routine named Bif5 passing 5 integer parameters:

```assembly
DLLAPPL CEEENTRY MAIN=YES,PPA=DLLPPA,AUTO=AUTOSZ
* Symbolic Register Definitions and Usage
R15 EQU 15 Entry point address
*
 THECALL CEEPCALL Bif5,(PARM1,PARM2,PARM3,PARM4,PARM5),VL,MF=(E,PARMS)
*
 SR R15,R15
 RETURN DS 0H
 CEETERM RC=(R15),MODIFIER=0
*
 DLLPPA CEEPPA
 LTORG
 CEEDSA
 CEECAA
 END DLLAPPL
```

Figure 164. Example calling routine named Bif5 passing 5 integer parameters:

**CEEPDDDA Macro — Define a Data Item in the Writeable Static Area (WSA)**

CEEPDDDA can be used to define data in WSA, and optionally specify it as either exported or imported data.

If the CEEPDDDA macro is followed by data constant(s), it is declared data, and must be followed by a subsequent CEEPDDDA invocation with only the END parameter to mark the end of the declared data. If there are no subsequent data constants, a reference will be created for the imported data.
Syntax

```
label CEEPDDA dataname, SCOPE= {LOCAL|EXPORT|IMPORT} EN
```

**label** Optional label beginning in column 1.

**dataname** Specifies the name of the data item. It is case sensitive and can be up to 255 characters in length. This entry name can reside in the same program object, or can be an exported DLL function.

**SCOPE= {LOCAL|EXPORT|IMPORT}**

Optional keyword parameter that results in the data being exported if SCOPE=EXPORT is specified and this instance of CEEPDDA is to declare data, or the data being imported if SCOPE=IMPORT is specified and this instance of CEEPDDA generates a reference to data (i.e. no data constants follow macro). The use of SCOPE=LOCAL can be used to declare data in WSA that is not exported.

**END** The use of CEEPDDA with the END parameter is used to indicate the end of this defined data item, and must be used in conjunction with an invocation of CEEPDDA with the SCOPE=EXPORT or SCOPE=LOCAL keyword parameter.

**Usage Notes:**

1. This macro requires the GOFF Assembler option.
2. This macro requires the binder to link-edit, and the RENT and DYNAM(DLL) binder options. You will also need the CASE(MIXED) binder option if the dataname is mixed case.
3. The output from the binder must be a PM3 (or higher) format program object, and therefore must reside in either a PDSE or the HFS.

For more details on DLLs, including full sample assembler DLL routines, see [43](#).

The following example illustrates how to export data from Assembler. The first exported data item is an integer with the initial value 123, and the second exported data item is the character string "Hello World" with a terminating NULL (x'00') character:

```
CEEPDDA D11Var,SCOPE=EXPORT
DC A(123)
CEEPDDA END
CEEPDDA D11Str,SCOPE=EXPORT
DC C'Hello World'
DC X'00'
CEEPDDA END
```

The following example illustrates how to import the variable named Biv1 into Assembler:

```
CEEPDDA Biv1,SCOPE=IMPORT
```
CEEPLDA Macro — Returns the Address of a Data Item Defined by CEEPDDA

CEEPLDA is used to obtain the address of a local, imported, or exported data item. The required *dataname* label will name the data item, is case sensitive, and can be up to 255 characters in length.

Registers 0, 14, and 15 are not preserved by this macro.

**Syntax**

```
label CEEPLDA—dataname—, REG=—register—
```

- **label**: Optional label beginning in column 1.
- **dataname**: Specifies the name of the data item whose address will be returned. It is case sensitive and can be up to 255 characters in length.
- **REG=**: The numeric value of the register to contain the address of the data identified by *dataname*. Registers 0, 14, and 15 cannot be used.

**Usage Notes:**

1. This macro requires the GOFF Assembler option.
2. This macro requires the binder to link-edit, and the RENT and DYNAM(DLL) binder options. You will also need the CASE(MIXED) binder option if the *dataname* is mixed case.
3. The output from the binder must be a PM3 (or higher) format program object, and therefore must reside in either a PDSE or the HFS.

For more details on DLLs, including full sample assembler DLL routines, see [43](#).

The following example illustrates how to obtain the address of an imported variable in WSA and store an integer value into it. This particular example uses a corresponding CEEPDDA instance for an imported variable, but an exported or local variable would also work.

```
* Obtain address of imported variable Biv1 in register 9
  CEEPLDA Biv1, REG=9
* Set value of imported variable to 123
  LA   R8,123
  ST   R8,0(,R9)
...  CEEPDDA Biv1,SCOPE=IMPORT
```

**Example of Assembler Main Routine**

[Figure 165 on page 504](#) shows a simple assembler main routine. In the example, the Language Environment environment is established, a message showing control is received in the routine, and the Language Environment environment terminates with a zero return code passed in R15 to the invoker.
If you write an assembler main routine, nominate the routine as a load module entry point using the END statement, as Figure 165 shows. Otherwise, you must explicitly declare the routine as the entry point at link-edit time.

```
*COMPILED UNIT: LEASMMN
*===================================================================
* A simple main assembler routine that brings up the LE/370 environment, prints a message in the main routine, and returns with a return code of 0, modifier of 0.

Invoking Callable Services from Assembler Routines

A Language Environment-conforming assembler routine called by C should not invoke a z/OS UNIX API.

The interface to a callable service is the same as the interface described above for assembler routines. An example of calling the CEEGTST (Get Heap Storage) callable service is shown in Figure 168.

A X’80000000’ placed in the last parameter address slot indicates that the fc (feedback code) parameter is omitted.

* * R12 = A(CAA)
* R13 = DSA
* This example is non-reentrant.
* LA R1,PLIST
  L R15,V(CEEGTST)
  BALR R14,R15
  :
PLIST DS 0D
DC A(HEAP_ID)
DC A(SIZE)
DC A(ADDR)
DC A(X’80000000’)
HEAP_ID DC F’0’ Heap ID for the user
SIZE DC F’256’ Size of storage to allocate
ADDR DC F’0’ Address of allocated storage

Figure 168. Sample Invocation of a Callable Service from Assembler
System Services Available to Assembler Routines

Language Environment provides a number of services that the host system typically provides. Each of these system-provided services belongs to one of three categories, depending on whether it can and ought to be used in Language Environment:

- The system-provided service can be used, but you must manage the resource; examples are ENQ and DEQ.
- The system-provided service can, but should not be used. The system-provided service might not have the desired effect. For example, instead of using GETMAIN and FREEMAIN, use the Language Environment dynamic storage callable services.
- The system-provided service should not be used. If you use this service, it directly interferes with the Language Environment environment. For example, any ESTAE or ESPIE that you issue interferes with Language Environment condition handling.

Whenever possible, non-Language Environment-conforming assembler routines should use the equivalent Language Environment services. A list of the equivalent services is provided in Table 62.

Table 62. Language Environment’s Equivalent Host Services

<table>
<thead>
<tr>
<th>Host Service</th>
<th>Language Environment Equivalent</th>
<th>Usability</th>
</tr>
</thead>
<tbody>
<tr>
<td>ABEND</td>
<td>Call CEE5GL with a severity 4 condition, call CEE3ABD, or have the assembler user exit request an abend at termination.</td>
<td>Host services can, but should not, be used. Use of equivalent Language Environment services is advised. ABEND can be used as a last resort.</td>
</tr>
<tr>
<td>ATTACH/DETACH/CHAP(^1)</td>
<td>No equivalent Language Environment function.</td>
<td>These services can be used.</td>
</tr>
<tr>
<td>ENQ/DEQ</td>
<td>No equivalent Language Environment function.</td>
<td>These services can be used.</td>
</tr>
<tr>
<td>(E)STAE/(E)SPIE/SETRP/STAX</td>
<td>Use Language Environment’s condition management callable services: CEEHDLR, CEEHDLU, and CEE5GL.</td>
<td>Host services should not be used; instances should be changed to use Language Environment condition management callable services. Otherwise, unpredictable results may occur.</td>
</tr>
<tr>
<td>EXEC CICS LOAD/DELETE</td>
<td>Use the Language Environment CEEFETCH assembler macro (see “CEEFETCH Macro — Dynamically Load a Language Environment-Conforming Routine” on page 494).</td>
<td>Host services can be used, but you must manage the loaded routines.</td>
</tr>
<tr>
<td>EXEC CICS XCTL/LINK</td>
<td>No equivalent Language Environment function.</td>
<td>These services can be used.</td>
</tr>
<tr>
<td>GETMAIN/FREEMAIN</td>
<td>For automatic storage (block-related), use Language Environment’s stack storage.</td>
<td>Host services can, but should not, be used. Use of equivalent Language Environment storage management services is advised.</td>
</tr>
<tr>
<td>EXEC CICS GETMAIN/EXEC CICS FREEMAIN</td>
<td>For non-block-related storage (that is, the storage persists beyond the current activation), use Language Environment heap storage.</td>
<td>Any heap storage allocated by Language Environment will automatically be freed at termination.</td>
</tr>

</tr>
<tr>
<td>SVC LINK</td>
<td>No equivalent Language Environment function</td>
<td>This service can be used. For compatibility, Language Environment supports the LINK boundary crossing and treats it as a new enclave.</td>
</tr>
<tr>
<td>WAIT/POST/EVENTS³</td>
<td>No equivalent Language Environment function.</td>
<td>Host services can be used.</td>
</tr>
<tr>
<td>WTO</td>
<td>Call CEEMOUT. This writes to the error log or the terminal.</td>
<td>Host services can be used.</td>
</tr>
<tr>
<td>XCTL</td>
<td>No equivalent Language Environment function.</td>
<td>Host services can, but should not, be used.</td>
</tr>
</tbody>
</table>

Notes:
1. When running with POSIX(ON), use the POSIX functions pthread_create and pthread_exit in place of the host system functions ATTACH and DETACH. You cannot use ATTACH, DETACH, or CHAP when running a PL/I multitasking application.
2. When running with POSIX(ON), use the C functions ALARM and SLEEP in place of the host system function STIMER.
3. When running with POSIX(ON), use the POSIX functions pthread_mutex_lock and pthread_mutex_unlock in place of the host system functions WAIT and POST.

Using the ATTACH Macro

[Figure 169 on page 511] illustrates the concept of performing an OS ATTACH to a C, C++, nonmultitasking PL/I, or COBOL program, and thus establishing a separate Language Environment run-time environment. For each ATTACH to a Language Environment-conforming routine, another Language Environment run-time environment is added to the MVS address space. In COBOL, this is called multitasking; COBOL RES multitasking is supported only when all of the COBOL programs are compiled with Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM, or COBOL/370 (not with OS/VS COBOL or VS COBOL II).
When running with POSIX(ON), use the POSIX function `pthread_create` in place of OS ATTACH to create a new thread.

Currently, each Language Environment environment supports one process. Within the process each enclave supports a single thread.

To make best use of the ATTACH macro, you need to be aware of:

- Whether you are using POSIX(ON) in a multithread environment. You must not use the ATTACH macro in this case. If you are running a PL/I multitasking application, you cannot use the ATTACH macro.
- Whether the Language Environment environments share any resources.
- The MVS affinity aspects of each routine. For example, if you OPEN a file in one TCB, you must CLOSE it in the same TCB.
- The concurrency aspects of each routine. For example, you must ensure that two routines do not attempt to make contradictory or destructive changes to a data base.
- The termination order of all routines, particularly those in a new Language Environment environment.
- The compiler options and link-edit options when using COBOL.

Sharing Resources

Unless you indicate otherwise, the environments share the same user files and message file. To avoid conflicting use of shared resources, you should specify different ddnames using the MSGFILE run-time option, and create distinctive user files for each environment.

**Note:** The ENQ suboption of the MSGFILE run-time option can be used to provide serialization around writes to the Message File. See 

Chapter 27. Assembler Considerations

z/OS Affinity Aspects

z/OS calls certain pairs of commands or procedures affinity aspects, and requires each member of the pair to be issued from the same TCB. For example, if you OPEN a file in one TCB, you must CLOSE it in the same TCB. You can process the file in as many environments as you wish; you simply need to open and close it in a single TCB. LOAD/DELETE is another example.
Assembler Considerations

A less obvious example is a DB2 table. You can update a DB2 table only in the same TCB in which it was created.

Concurrency Aspects
Concurrency aspects include which routines have access to shared resources, and the timing of changes to those resources. Because Language Environment does not provide services to lock files, to serialize access to shared resources, or to synchronize changes to shared resources, you must manage the concurrency aspects of your environments.

Termination Order
Language Environment does not coordinate termination order between multiple environments. Your routines are exited properly if you adhere to the hierarchical structure created by the TCB structure.

COBOL Considerations
To run COBOL programs in more than one task with Language Environment, the COBOL programs must be Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM, or COBOL/370. Running VS COBOL II programs in more than one task is not supported. When you use COBOL programs in more than one task, it is recommended that the COBOL programs be compiled with the RENT compiler option, and that the load modules be linked as REUS and RENT.

If a COBOL program running in one task dynamically calls a COBOL program that has already been dynamically called from another task, then the called program must be:
- Compiled with the RENT compiler option, or
- Compiled with the NORENT compiler option and link-edited with the NORENT and NOREUS linkage editor options.

Each copy of a COBOL program in each task will have its own unique copy of WORKING-STORAGE; you cannot share WORKING-STORAGE between tasks.

For example (see Figure 170), if a COBOL program calls an assembler program, which starts a new Subtask B, and COBOL program CBL3 in the new subtask dynamically calls COBOL program CBL2 which was previously dynamically called in the main task, then CBL2 must not be link-edited with the RENT or REUS link-edit options unless it is compiled with the RENT compiler option.

```
MAIN
  task : Subtask B
    |
    CBL1
      |
        V
        CBL2 <-----------------
        |
        |
        V
        ASMA----(attach)---->CBL3
```

*Figure 170. A dynamically called COBOL program which dynamically calls another COBOL program*
Using the SVC LINK Macro

If you issue an SVC LINK, a new enclave is created. See “Creating child enclaves using SVC LINK” on page 557 for more information about nested enclaves created using the SVC LINK macro.
Chapter 30. Using preinitialization services

You can use preinitialization to enhance the performance of your application. Preinitialization lets an application initialize an HLL environment once, perform multiple executions using that environment, and then explicitly terminate the environment. Because the environment is initialized only once (even if you perform multiple executions), you free up system resources and allow for faster responses to your requests.

This chapter describes the Language Environment-supplied routine, CEEPIPI, that provides the interface for preinitialized routines. Using CEEPIPI, you can initialize an environment, invoke applications, terminate an environment, and add an entry to the Preinitialization table (PreInit table). (The PreInit table contains the names and entry point addresses of routines that can be executed in the preinitialized environment.)

This chapter also describes reentrancy considerations for a preinitialized environment, XPLINK considerations, user exit invocation, stop semantics, service routines, and an example of CEEPIPI invocation.

Prior to the introduction of a 'common' run-time environment, introduced with Language Environment, some of the individual languages had their own form of preinitialization. This older form of preinitialization is supported by Language Environment, but it is not strategic. The following is a list of these older forms of preinitialization and some considerations for their use:

- **C**
  Language Environment supports the prior form of C preinitialization, through the use of an Extended Parameter List. For more information about this interface, see [z/OS C/C++ Programming Guide](https://www.ibm.com/support/knowledgecenter/POWER7/programming/c/c++/zocppg/)

- **C++**
  There is no prior form of preinitialization for C++.

- **COBOL**
  Language Environment supports the prior form of COBOL preinitialization, RTEREUS, ILBOSTP0, and IGZERRE. For more information about these interfaces, see [COBOL for OS/390 & VM and COBOL for MVS & VM Compiler and Run-Time Migration Guides](https://www.ibm.com/support/knowledgecenter/POWER7/programming/obiz/cobol/g/dmzcmv00/). This prior form of COBOL preinitialization cannot be used at the same time that Language Environment preinitialization is used.

- **Fortran**
  There is no prior form of preinitialization for Fortran.

- **PL/I**
  Language Environment supports the prior form of PL/I preinitialization, through the use of an Extended Parameter List. For more information about this interface, see [PL/I for MVS & VM Programming Guide](https://www.ibm.com/support/knowledgecenter/POWER7/programming/c/c++/zocppg/). This prior form of PL/I preinitialization does not support PL/I multitasking applications.

**Restriction:** On z/OS.e, these prior forms of preinitialization are not supported. Only the strategic Language Environment form of preinitialization is supported.
Understanding the basics

From a non-Language Environment-conforming driver (such as assembler) you can use Language Environment preinitialization facilities to create and initialize a common run-time environment, execute applications written in a Language Environment-conforming HLL multiple times within the preinitialized environment, and terminate the preinitialized environment. Language Environment provides a preinitialized interface to perform these tasks.

In the preinitialized environment, the first routine to execute can be treated as either the main routine or a subroutine of that execution instance. Language Environment provides support for both of these types of preinitialized routines:
- Executing one main routine multiple times
- Executing subroutines multiple times

Language Environment preinitialization is commonly used to enhance performance for repeated invocations of an application or for a complex application where there are many repetitive requests and where fast response is required. For instance, if an assembler routine invokes either a number of Language Environment-conforming HLL routines or the same HLL routine a number of times, the creation and termination of that HLL environment multiple times is needlessly inefficient. A more efficient method is to create the HLL environment only once for use by all invocations of the routine.

Using preinitialization

The interface for preinitialized routines is a loadable routine called CEEPIPI. This routine is loaded as an RMODE(24) / AMODE(ANY) routine and returns in the AMODE of its caller when the request is satisfied.

CEEPIPI handles the requests and provides services for environment initialization, application invocation, and environment termination. All requests for services by CEEPIPI must be made from a non-Language Environment environment. ([Preinitialization interface” on page 522](#)) contains a detailed description and information about how to invoke each of these services.) The parameter list for CEEPIPI is an OS standard linkage parameter list. Each request to CEEPIPI is identified by a function code that describes the CEEPIPI service and that is the first parameter in the parameter list. The function code is a fullword integer (for example, 1 = init_main, 2 = call_main).

The preinitialization services offered under Language Environment are listed in Table 64 on page 522 Preinitialization services do not support PL/I multitasking applications.

An example assembler program in section “An example program invocation of CEEPIPI” on page 549 illustrates invocation of CEEPIPI for the function codes init_sub, call_sub, and term.

Using the PreInit table

Language Environment uses the PreInit table to identify the routines that are candidates for execution in the preinitialized environment, as well as optionally to load the routine when it is called. It is possible to have an empty PreInit table with no entries. The PreInit table contains the names and the entry point addresses of each routine that can be executed within the preinitialized environment. Candidate
routines can be present in the table when the init_main or init_sub functions are invoked, or can be added to the table using (add_entry).

When the entry point address is supplied either as an entry in the initial PreInit table provided with initialization functions, or as specified on the add_entry function, the high order bit of the address must be set to indicate the addressing mode for the routine. If the high order bit is OFF the routine is called in 24 bit addressing mode and the address must be a valid 24 bit address. If the high order bit is ON the routine is called in 31 bit addressing mode and the address must be a valid 31 bit address.

**C considerations**
C routines that are the target of (call_main) or (call_sub) must be z/OS C routines.

**C++ considerations**
The preinitialization routines (call_main) or (call_sub) can support C++ applications.

**COBOL considerations**
COBOL programs that are the target of (call_main) or (call_sub) must be Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM, or COBOL/370 programs.

**Fortran considerations**
Fortran routines cannot be the target of a CEEPIPI call.

**PL/I considerations**
PL/I routines that are the target of (call_main) or (call_sub) must be VisualAge PL/I or PL/I for MVS & VM routines. OS PL/I Version 1 and OS PL/I Version 2 routines can run in the preinitialized environment only when called from PL/I routines that are the target of (call_main) or (call_sub).

**Macros that generate the PreInit table**
Language Environment provides the following assembler macros to generate the PreInit table for you: CEEXPIT, CEEXPITY, and CEEXPITS.

**CEEXPIT:** CEEXPIT generates a header for the PreInit table.

```
Syntax:

                   table_name--CEEXPIT
  
  ABEND
  NOSTOR=RC

Table_name
Assembler symbolic name assigned to the first word in the PreInit table. This is the value that should be used as the cexpitable_addr parameter in a (init_main) or a (init_sub) call.

NOSTOR=ABEND
 Indicates that the system is to issue an abend if it cannot obtain storage for the preinitialization environment. This is the default.

NOSTOR=RC
 Indicates that the system is to issue a return code if it cannot obtain storage for the preinitialization environment.
```
CEEXPITY: CEEXPITY generates an entry within the PreInit table.

**Syntax**

```
CEEXPITY, [name], [entry_point]
```

**name**
The first eight characters of the load name of a routine that can be invoked within the Language Environment preinitialized environment.

**entry_point**
The address of the load module that is to be invoked, or 0, to indicate that the module is to be dynamically loaded.

The high-order bit of the entry_point address must be set to indicate the addressing mode for the routine. If the high-order bit is OFF, the routine is called in 24 bit addressing mode and the address must be a valid 24 bit address. If the high-order bit is ON, the routine is called in 31 bit addressing mode and the address must be a valid 31 bit address.

You have the option of specifying either, both, or neither of the parameters:

- If name is omitted and entry_point is present, the comma must be present.
- If both parameters are omitted, the entry is a candidate for assignment to the PreInit table by a call to (add_entry).
- If both parameters are present, name is ignored and entry_point is used as the start of the routine.

Each invocation of the CEEXPITY macro generates a row in the PreInit table. The first entry is row 0, the second is row 1, and so on.

CEEXPITS: CEEXPITS identifies the end of the PreInit table.

This macro has no parameters.

**Reentrancy considerations**

You can make multiple calls to main routines by invoking CEEPIPI services and making multiple requests from a single PreInit table. In general, you should specify only reentrant routines for multiple invocations, or you might get unexpected results.

For example, if you have a reentrant C main program that is invoked using (call_main) and that uses external variables, then when your routine is invoked again, the external variables are re-initialized. Multiple executions of a reentrant main routine are not influenced by a previous execution of the same routine.
However, if you have a nonreentrant C main program that is invoked using
\texttt{call\_main} and that uses external variables, then when your routine is invoked
again, the external variables can potentially contain last-used values. Local
variables (those contained in the object code itself) might also contain last-used
values. If main routines are allowed to execute multiple times, a given execution of
a routine can influence subsequent executions of the same routine.

If you are calling \texttt{init\_sub}, \texttt{init\_sub\_dp}, or \texttt{add\_entry} for C/C++, the routines can
either be naturally reentrant or may be compiled RENT and made reentrant by
using the z/OS C Prelinker Utility. If the subroutine is made reentrant using the
z/OS C Prelinker Utility, multiple instances of the same subroutine are influenced by
the previous instance of the same subroutine.

If you have a nonreentrant COBOL program that is invoked using \texttt{(call\_main)},
condition IGZ0044S is signalled when the routine is invoked again.

**PreInit XPLINK considerations**

Language Environment preinitialization services (PreInit) support programs that
have been compiled XPLINK. Specifically, it allows programs and subroutines that
have been compiled XPLINK to be defined in the PreInit table. The following
guidelines are provided for this new option:

- XPLINK CEEPIPI subroutines must be fetchable. For C programs, this is done
  using the \#pragma linkage (fetchable) statement. For more details on fetchable
  subroutines, refer to the documentation on fetch() in \textit{Z/OS C/C++ Run-Time}
  Library Reference

- Non-XPLINK PreInit programs can run in an XPLINK PreInit environment, but
  there may be performance degradation since non-XPLINK programs will be
  required to execute linkage-switching glue code. If possible, consider having
  separate PreInit environments for running XPLINK and non-XPLINK programs.

- If a PreInit environment has been initialized as a non-XPLINK environment and
  either the main() function is XPLINK or the XPLINK(ON) run-time option has
  been specified, then the PreInit environment will be rebuilt as an XPLINK
  environment. This is a one-time occurrence that can not be undone.

**Creating an XPLINK environment versus a non-XPLINK environment**

When initializing a PreInit environment, you can select to create an XPLINK or a
non-XPLINK environment. There are 3 methods used to initialize a PreInit
environment; \texttt{init\_main}, \texttt{init\_sub}, and \texttt{init\_sub\_dp}. In each case, a token of the
preinitialized environment is passed back to the customer PreInit driver program.
This token ID is used and passed as input when executing PreInit programs. The
following rules will determine if the initialized PreInit environment will be XPLINK or
non-XPLINK. Note that you can make a one-time dynamic change in the PreInit
environment from non-XPLINK to XPLINK by using \texttt{(call\_main)} to an XPLINK
\texttt{main()}.

\texttt{init\_main}: (Input: PreInit table pointer, no run-time options are passed as input)
- If the first program in the customer PreInit table is an XPLINK program, then an
  XPLINK environment will be initialized.
- If the first program in the PreInit table is a non-XPLINK program, then a
  non-XPLINK environment will be initialized.
- If the PreInit table is empty at initialization time, then a non-XPLINK environment
  will be initialized.
Preinitialization Services

init_sub: (Input: Preinit table pointer, and run-time options)
- If the first program in the customer PreInit table is an XPLINK program, then an
  XPLINK environment will be initialized.
- If the run-time options are passed as input and the XPLINK option is specified as
  XPLINK(ON), then an XPLINK environment will be initialized.
- If neither of the above are true (the first program in the customer PreInit table is
  a non-XPLINK program and the XPLINK run-time option is off or not specified),
  then a non-XPLINK environment will be initialized.

Notes:
1. The run-time options you specify will apply to all of the subroutines that are
called by (call_sub) function. This includes options such as XPLINK. Therefore,
all of your subroutines must have the same characteristics and requirements
needed for these run-time options.
2. If this is a non-XPLINK sub environment, then do not allow an XPLINK
subroutine to be added to the table.

init_sub_dp: (Input: PreInit table pointer, and run-time options)
- If the first program in the customer PreInit table is an XPLINK program, then an
  XPLINK environment will be initialized.
- If the run-time options are passed as input and the XPLINK option is specified as
  XPLINK(ON), then an XPLINK environment will be initialized.
- If neither of the above are true (the first program in the customer PreInit table is
  a non-XPLINK program and the XPLINK run-time option is off or not specified),
  then a non-XPLINK environment will be initialized.

Note: The run-time options you specify will apply to all of the subroutines that are
called by (call_sub) function. This includes options such as XPLINK.
Therefore, all of your subroutines must have the same characteristics and
requirements needed for these run-time options.

User exit invocation

User exits are invoked for initialization and termination during calls to CEEPIPI as
shown in Table 63.

<table>
<thead>
<tr>
<th>Function</th>
<th>When Invoked</th>
</tr>
</thead>
</table>
| Assembler user exit for first enclase initialization | • (init_sub)  
| | • (init_sub_dp)  
| | • (call_main)  
| | • (call_sub) or (call_sub_addr) or (call_sub_addr) ended with stop semantics (see "Stop semantics" on page 521) |
| HLL user exit | • (init_sub)  
| | • (init_sub_dp)  
| | • (call_main)  
| | • (call_sub) or (call_sub_addr) or (call_sub_addr) ended with stop semantics |
Table 63. Invocation of User Exits during Process and Enclave Initialization and Termination (continued)

<table>
<thead>
<tr>
<th>Function</th>
<th>When Invoked</th>
</tr>
</thead>
<tbody>
<tr>
<td>C atexit() functions</td>
<td>• (call_main)</td>
</tr>
<tr>
<td></td>
<td>• (call_sub) or (call_sub_addr), which ended stop semantics.</td>
</tr>
<tr>
<td></td>
<td>• (term) for environment created with (init_sub) or (init_sub_dp), if the last (call_sub) or (call_sub_addr) did not end with stop semantics</td>
</tr>
<tr>
<td>Assembler user exit for first enclave termination</td>
<td>• (call_main)</td>
</tr>
<tr>
<td></td>
<td>• (call_sub) or (call_sub_addr), which ended stop semantics</td>
</tr>
<tr>
<td></td>
<td>• (term) for environment created with (init_sub) or (init_sub_addr) if the last (call_sub) or (call_sub_addr) did not end with stop semantics</td>
</tr>
<tr>
<td>Assembler user exit for process termination</td>
<td>• (term)</td>
</tr>
</tbody>
</table>

The CEEBXITA assembler user exit and CEEBINT HLL user exit that are used with the environment are taken from the first valid entry in the PreInit table. Any occurrences of CEEBXITA or CEEBINT in any other PreInit table entries, or in load modules used for call_sub_addr-type calls, are ignored.

Stop semantics

When one of the following is issued within the preinitialized environment for subroutines:

• C exit(), abort(), or signal handling function specifying a normal or abnormal termination
• COBOL STOP RUN statement
• PL/I STOP or EXIT

or when an unhandled condition causes termination of the (only) thread, the logical enclave is terminated. The process level of the environment is retained. Language Environment does not delete those entries that were loaded explicitly by Language Environment during the preinitialization processing.

Attention: The logical enclave is re-initialized at the next call_sub or call_sub_addr. If, at that time, the first valid entry in the PreInit table is different than when the enclave was last initialized, the assembler user exit (CEEBXITA), HLL user exit (CEEBINT), and/or programmer default run-time options (CEEUOPT) used during the enclave re-initialization might be different. PreInit subroutine initialization uses these external references only when associated with the first valid entry in the PreInit table. Therefore, when using PreInit subroutine environments and you want consistent enclave initialization behavior across the stop semantics, you need to ensure the first valid entry in the PreInit table does not change, especially when it contains the aforementioned external references.
Preinitialization Services

Preinitialization interface

The following section describes how to invoke the PreInit interface, CEEPIPI, to perform the following tasks:

- Initialization
- Application invocation
- Termination
- Addition of an entry to the PreInit table
- Deletion of a main entry from the PreInit table
- Identification of an entry in the PreInit table

The PreInit services offered under Language Environment, via CEEPIPI are listed in Table 64.

Table 64. Preinitialization Services Accessed Using CEEPIPI

Initialization

Language Environment supports three forms of preinitialized environments. The first, supports the execution of main routines. The second, supports the execution of subroutines. The third is a special form of the second, that allows multiple preinitialized environments, for executing subroutines, to be created within the same address-space.

The primary difference between these environments is the amount of Language Environment initialization (and termination) that occurs on each application invocation call. With an environment that supports main routines, most of the application’s execution environment is reinitialized with each invocation. With an environment that supports subroutines, very little of the execution environment is reinitialized with each invocation. This difference has its advantages and disadvantages.

Main environment:

Advantages:
• A new, pristine environment is created
• Run-Time options can be specified for each application

Disadvantages:
• Poorer performance

Sub environment:

Advantages:
• Best performance

Disadvantages
• The environment is left in what ever state the previous application left it in
• Run-Time options cannot be changed

(init_main) — initialize for main routines
The invocation of this routine:
• Creates and initializes a new common run-time environment (process) that allows the execution of main routines multiple times
• Sets the environment dormant so that exceptions are percolated out of it
• Returns a token identifying the environment to the caller
• Returns a code in Register 15 indicating whether an environment was successfully initialized
Syntax

```
CALL CEEPIPI((init_main, ceexptbl_addr, service_rtns, token))
```

init_main (input)
A fullword function code (integer value = 1) containing the init_main request.

ceexptbl_addr (input)
A fullword containing the address of the PreInit table to be used during initialization of the new environment. Language Environment does not alter the user-supplied copy of the table. If an entry address is zero and the entry name is non-blank, Language Environment searches for the routine (in the LPA, saved segment, or nucleus) and dynamically loads it. Language Environment places the entry address in the corresponding slot of a Language Environment-maintained table.

Language Environment uses the high-order bit of the entry address to determine what AMODE to use when calling the routine. If the entry address is zero, and the entry name is supplied, Language Environment uses the AMODE returned by the system loader. If the entry address is supplied, you must provide the AMODE in the high-order bit of the address.

service_rtns (input)
A fullword containing the address of the service routine vector or 0, if there is no service routine vector. See “Service routines” on page 542 for more information.

token (output)
A fullword containing a unique value used to represent the environment.

The token should be used only as input to additional calls to CEEPIPI, and should not be altered or used in any other manner.

Return Codes:
Register 15 contains a return code indicating if an environment was successfully initialized. Possible return codes are:

- 0 A new environment was successfully initialized.
- 4 The function code is not valid.
- 8 All addresses in the table were not resolved. This can occur if a LOAD failure was encountered or a routine within the table was generated by a non-Language Environment-conforming HLL.
- 12 Storage for the preinitialization environment could not be obtained.
- 16 CEEPIPI was called from an active environment.
- 32 An unhandled error condition was encountered. This error is a result of a program interrupt or other abend that occurred that prevented the preinitialization services from completing.

Abend codes:

U4093-DC
Issued when a language that is not supported on the z/OS.e operating system is found during setup of the PreInit table.

Usage Notes:
Preinitialization Services

- The assembler user exit (CEEBXITA), HLL user exit (CEEBINT), and programmer defaults (CEEVOPT) that are used to initialize the environment are taken from the first valid entry in the PreInit table. Any occurrences of CEEBXITA, CEEBINT, and CEEVOPT in other PreInit table entries are ignored.
- If a program in the PreInit table failed to load (return code 8), the identify_attributes CEEPIPI function can be used to help determine what table entry address did not resolve.

XPLINK considerations:
- If the environment being initialized is to be an XPLINK environment then the first program in the PreInit table must be an XPLINK module.
- If there is no entry in the PreInit table or if the first module is a non-XPLINK program, a non-XPLINK environment will be initialized.
- It is possible to change the environment from a non-XPLINK to an XPLINK environment when doing a call_main. For more details, see call_main.

(init_sub) — initialize for subroutines
The invocation of this routine:
- Creates and initializes a new common run-time environment (process and enclave) that allows the execution of subroutines multiple times
- Sets the environment dormant so that exceptions are percolated out of it
- Returns a token identifying the environment to the caller
- Returns a code in Register 15 indicating whether an environment was successfully initialized
- Ensures that when the environment is dormant, it is immune to other Language Environment enclaves that are created or terminated

Syntax

```
CALL CEEPIPI (init_sub, ceexptbl_addr, service_rtns, ...
CALL runtime_opts, token)
```

init_sub (input)
A fullword function code (integer value = 3) containing the init_sub request.

ceexptbl_addr (input)
A fullword containing the address of the PreInit table to be used during initialization of the new environment. Language Environment does not alter the user-supplied copy of the table. If an entry address is zero and the entry name is non-blank, Language Environment searches for the routine (in the LPA, saved segment, or nucleus) and dynamically loads it. Language Environment then places the entry address in the corresponding slot of a Language Environment-maintained table.

Language Environment uses the high-order bit of the entry address to determine what AMODE to use when calling the routine. If the entry address is zero, and the entry name is supplied, Language Environment uses the AMODE returned by the system loader. If the entry address is supplied, you must provide the AMODE in the high-order bit of the address.
Preinitialization Services

`service_rtns (input)`
A fullword containing the address of the service routine vector. It contains 0 if there is no service routine vector. See [“Service routines” on page 542](#) for more information.

`runtime_opts (input)`
A fixed-length 255-character string containing run-time options (see [z/OS Language Environment Programming Reference](#) for a list of run-time options that you can specify).

**Notes:**
1. The run-time options you specify will apply to all of the subroutines that are called by the (call_sub) function. This includes options such as POSIX. Therefore, all of your subroutines must have the same characteristics and requirements needed for these run-time options.
2. If the Language Environment being initialized is a non-XPLINK environment, then all of your subroutines must be non-XPLINK subroutines.

`token (output)`
A fullword containing a unique value used to represent the environment. The `token` should be used only as input to additional calls to CEEPIPI, and should not be altered or used in any other manner.

**Return Codes:** Register 15 contains a return code indicating the success or failure of the call. Possible return codes are:

- 0 A new environment was successfully initialized.
- 4 The function code is not valid.
- 8 All addresses in the table were not resolved. This can occur if a LOAD failure was encountered, a routine within the table was not generated by a Language Environment-conforming HLL, or a C or PL/I routine within the table was not fetchable.
- 12 Storage for the preinitialization environment could not be obtained.
- 16 CEEPIPI was called from an active environment.
- 32 An unhandled error condition was encountered. This error is a result of a program interrupt or other abend that occurred that prevented the preinitialization services from completing.
- 40 An entry in the PreInit table is an XPLINK subroutine and the environment is a non-XPLINK sub environment. This entry is not valid.

**Abend Codes:**

**U4093-DC**
Issued when a language that is not supported on the z/OS.e operating system is found during setup of the PreInit table.

**Usage Notes:**

- The assembler user exit (CEEBXITA), HLL user exit (CEEBINT), and programmer defaults (CEEUOPT) that are used to initialize the environment are taken from the first valid entry in the PreInit table. Any occurrences of CEEBXITA, CEEBINT, and CEEUOPT in other Preinit table entries are ignored.
- If a program in the PreInit table failed to load (return code 8 or 40), the `identify_attributes` CEEPIPI function can be used to help determine what table entry address did not resolve.

**XPLINK considerations:**

- If the first program in the customer PreInit table is an XPLINK program, then an XPLINK environment will be initialized.
Preinitialization Services

- If the run-time options are passed as input and the XPLINK option is specified as XPLINK(ON), then an XPLINK environment will be initialized.
- If neither of the above are true (the first program in the customer PreInit table is a non-XPLINK program and the XPLINK run-time option is off or not specified), then a non-XPLINK environment will be initialized.

Notes:
1. The run-time options you specify will apply to all of the subroutines that are called by (call_sub) function. This includes options such as XPLINK. Therefore, all of your subroutines must have the same characteristics and requirements needed for these run-time options.
2. If this is a non-XPLINK sub environment, then do not allow an XPLINK subroutine to be added to the table.

(init_sub_dp) — initialize for subroutine (multiple environment)
The invocation of this routine:
- Creates and initializes a new Language Environment process and enclave to allow the execution of subroutines multiple times
- Sets the environment dormant so that exceptions are percolated out of it
- Returns a token identifying the environment to the caller
- Returns a code in Register 15 indicating whether an environment was successfully initialized
- Ensures that the environment tolerates the existence of multiple Language Environment enclaves
- Ensures that when the environment is dormant, it is immune to other Language Environment enclaves that are created or terminated

Multiple environments can be established only by using (init_sub_dp) as opposed to (init_sub), which can establish only a single environment.

Syntax

\[
\text{CALL CEEPIPI} \left( \text{init_sub_dp}, \text{ceexptbl_addr}, \text{service_rtns}, \cdots \right) \text{ runtime_opts, } \text{token} \\
\]

init_sub_dp (input)
A fullword function code (integer value = 9) containing the init_sub_dp request.

ceexptbl_addr (input)
A fullword containing the address of the PreInit table to be used during initialization of the new environment. Language Environment does not alter the user-supplied copy of the table. If an entry address is zero and the entry name is non-blank, Language Environment searches for the routine (in the LPA, saved segment, or nucleus) and dynamically loads it. Language Environment then places the entry address in the corresponding slot of a Language Environment-maintained table.

Language Environment uses the high-order bit of the entry address to determine what AMODE to use when calling the routine. If the entry address is zero, and the entry name is supplied, Language Environment uses the AMODE returned by the system loader. If the entry address is supplied, you must provide the AMODE in the high-order bit of the address.
Preinitialization Services

**service_rtns (input)**
A fullword containing the address of the service routine vector. It contains 0 if there is no service routine vector. See "Service routines" on page 542 for more information.

**runtime_opts (input)**
A fixed-length 255-character string containing run-time options (see [z/OS Language Environment Programming Reference](https://www.ibm.com/support/docview.wss?rs=29&uid=swg27031241) for a list of run-time options that you can specify).

**Notes:**
1. The run-time options you specify will apply to all of the subroutines that are called by the (call_sub) function. This includes options, such as POSIX. Therefore, all of your subroutines must have the same characteristics and requirements needed for these run-time options.
2. If you want to run XPLINK routines in a PreInit sub environment, you must specify the XPLINK(ON) run-time option field when you create the sub environment by calling CEEPIPI(init_sub). You can not run XPLINK routines in a sub environment when run-time option XPLINK(OFF) is in effect.

**token (output)**
A fullword containing a unique value used to represent the environment.

The token should be used only as input to additional calls to CEEPIPI, and should not be altered or used in any other manner.

**Return Codes:** Register 15 contains a return code indicating the success or failure of the call. Possible return codes are:

- **0** A new environment was successfully initialized.
- **4** The function code is not valid.
- **8** All addresses in the table were not resolved. This can occur if a LOAD failure was encountered or a routine within the table was not generated by a Language Environment-conforming HLL.
- **12** Storage for the preinitialization environment could not be obtained.
- **32** An unhandled error condition was encountered. This error is a result of a program interrupt or other abend that occurred that prevented the preinitialization services from completing.
- **40** An entry in the PreInit table is an XPLINK subroutine and the environment is a non-XPLINK sub environment. This entry is not valid.

**Abend Codes:**

**U4093-DC**
Issued when a language that is not supported on the z/OS.e operating system is found during setup of the PreInit table.

**Usage Notes:**
- The assembler user exit (CEEBXITA), HLL user exit (CEEBINT), and programmer defaults (CEEUOPT) that are used to initialize the environment are taken from the first valid entry in the PreInit table. Any occurrences of CEEBXITA, CEEBINT, and CEEUOPT in other PreInit table entries are ignored.
- COBOL, PL/I, and C routines must be compiled RENT to participate in this environment.
- You can direct MSGFILE output to either a spool or to a unique file.
- C memory files are not shared across multiple environments.
- If the (init_sub_dp,...) interface is used to create additional environments, neither the existing environment, nor the one trying to be created can be POSIX(ON).
Preinitialization Services

- If a program in the PreInit table failed to load (return code 8 or 40), the `identify_attributes` CEEPIPI function can be used to help determine what table entry address did not resolve.

**XPLINK considerations:**
- If the first program in the customer PreInit table is an XPLINK program, then an XPLINK environment will be initialized.
- If the run-time options are passed as input and the XPLINK option is specified as XPLINK(ON), then an XPLINK environment will be initialized.
- If neither of the above are true (the first program in the customer PreInit table is a non-XPLINK program and the XPLINK run-time option is off or not specified), then a non-XPLINK environment will be initialized.

**Note:** The run-time options you specify apply to all of the subroutines that are called by (call_sub_dp) function. This includes options such as XPLINK. Therefore, all of your subroutines must have the same characteristics and requirements needed for these run-time options.

**Application invocation**

Language Environment provides facilities to invoke either a main routine or subroutine. When invoking main routines, the environment must have been initialized using the `init_main` function code. Similarly, when invoking subroutines, the environment must have been initialized with the `init_sub` or `init_sub_dp` function codes.

**call_main** — invocation for main routine

This invocation of CEEPIPI invokes as a main routine the routine that you specify. The common execution environment identified by `token` is activated before the called routine is invoked, and after the called routine returns, the environment is dormant.

At termination, the currently active HLL event handlers are driven to enforce language semantics for the termination of an application such as closing files and freeing storage. The process level is made dormant rather than terminated. The thread and enclave levels are terminated. The assembler user exit is driven with the function code for first enclave termination. (For more information about user exits, see [Chapter 28, “Using Run-Time User Exits,” on page 457.]

**Syntax**

```
CALL CEEPIPI(call_main, ceexptl_index, token, runtime_opts, parm_ptr, enclave_return_code, enclave_reason_code, appl_feedback_code)
```

**call_main (input)**

A fullword function code (integer value = 2) containing the call_main request.

**ceexptl_index (input)**

A fullword containing the row number within the PreInit table of the entry that should be invoked. The index starts at 0.
Preinitialization Services

Note that each invocation of the CEXPITY macro generates a row in the Preinit table. The first entry is row 0, the second is row 1 and so on. A call to (add_entry) to add an entry to the PreInit table also returns a row number in the ceexitbl_index parameter.

token (input)
A fullword with the value of the token returned by (init_main) when the common run-time environment is initialized. The token must identify a previously preinitialized environment that is not active at the time of the call.

runtime_opts (input)
A fixed-length 255-character string containing run-time options. (See z/OS Language Environment Programming Reference for a list of run-time options that you can specify.)

parm_ptr (input)
A fullword parameter list pointer or 0 (zero) that is placed in register 1 when the main routine is executed.

The parameter list that is passed must be in a format that HLL subroutines expect (for example, in an argc, argv format for C routines).

enclave_return_code (output)
A fullword containing the enclave return code returned by the called routine when it finished executing. For more information about return codes, see "Managing return codes in Language Environment" on page 151.

enclave_reason_code (output)
A fullword containing the enclave reason code returned by the environment when the routine finished executing. For more information about reason codes, see "Managing return codes in Language Environment" on page 151.

appl_feedback_code (output)
A 96-bit condition token indicating why the application terminated.

Return Codes: A return code is provided in register 15 and can contain the following values:

0  The environment was activated and the routine called.
4  The function code is not valid.
8  CEEPIPI was called from a Language Environment-conforming HLL.
12  The indicated environment was initialized for subroutines. No routine was executed.
16  The token is not valid.
20  The index points to an entry that is not valid or empty.
24  The index that was passed is outside of the range of the table.
32  An unhandled error condition was encountered. This error is a result of a program interrupt or other abend that occurred that prevented the preinitialization services from completing.

The user return code and Language Environment return code modifier are set to zero prior to invoking the target routine.

Usage Notes:
- The NOEXECOPS and CBLOPTS run-time options (see z/OS Language Environment Programming Reference) are ignored since the parameter inbound to the application and the run-time options are separated already. Therefore, NOEXECOPS and CBLOPTS do not affect the parameter string format. See "C PLIST and EXECOPS Interactions" on page 595 for more information.
For more information about return codes, see "Managing return codes in Language Environment" on page 151.

(call_sub) — invocation for subroutines
This invocation of CEEPIPI invokes as a subroutine the routine that you specify. The common run-time environment identified by token is activated before the called routine is invoked, and after the called routine returns, the environment is dormant.

The enclave is terminated when an unhandled condition is encountered or a STOP statement is executed. (See "Stop semantics" on page 521 for more information.) However, the process level is maintained. The next call to (call_sub) initializes a new enclave.

```
CALL CEEPIPI(call_sub, ceexptl_index, token, parm_ptr, sub_ret_code, sub_reason_code, sub_feedback_code)
```

call_sub (input)
A fullword function code (integer value = 4) containing the call_sub request for a subroutine.

ceexptbl_index (input)
A fullword containing the row number of the entry within the PreInit table that should be invoked; the index starts at 0.

Note: If the token pointing to the previously preinitialized environment is a non-XPLINK environment and the subprogram to be invoked is XPLINK, then a Return Code of 40 will be returned because this is not valid.

token (input)
A fullword with the value of the token returned when the common run-time environment is initialized. This token is initialized by the (init_sub) or (init_sub_dp).

The token must identify a previously preinitialized environment that is not active at the time of the call. You must not alter the value of the token.

Note: If the token pointing to the previously preinitialized environment is a non-XPLINK environment and the subprogram to be invoked is XPLINK a Return Code of 40 will be returned because this is not valid.

parm_ptr (input)
A parameter list pointer or 0 (zero) that is placed in register 1 when the routine is executed.

C users need to follow the subroutine linkage convention for C — assembler ILC applications, as described in z/OS C/C++ Programming Guide.

sub_ret_code (output)
The subroutine return code. If the enclave is terminated due to an unhandled condition, a STOP statement, or EXIT statement (or an exit() function), this contains the enclave return code for termination.

sub_reason_code (output)
The subroutine reason code. This is 0 for normal subroutine returns. If the
enclave is terminated due to an unhandled condition, a STOP statement, or EXIT statement (or an exit() function), this contains the enclave reason code for termination.

$sub\_feedback\_code$ (output)
The feedback code for enclave termination. This is the CEE000 feedback code for normal subroutine returns. If the enclave is terminated due to an unhandled condition, a STOP statement, or EXIT statement (or an exit() function), this contains the enclave feedback code for termination.

Return Codes: A return code is provided in register 15 and can contain the following values:
- 0: The environment was activated and the routine called.
- 4: The function code is not valid.
- 8: CEEPIPI was called from a Language Environment-conforming HLL.
- 12: The indicated environment was initialized for main routines. No routine was executed.
- 16: The $token$ is not valid.
- 20: The index points to an entry that is not valid or empty.
- 24: The index passed is outside the range of the table.
- 28: The enclave was terminated but the process level persists.

This value indicates the enclave was terminated while the process was retained. This can occur due to a STOP statement being issued or due to an unhandled condition. The $sub\_ret\_code$, $sub\_reason\_code$, and $sub\_feedback\_code$ indicate this action.

- 40: The subprogram was an XPLINK program and the preinitialized environment is non-XPLINK. This is not valid.

Usage Notes:
- The enclave terminates if the subroutine issues a STOP statement, EXIT statement (or an exit() function), or if there is an unhandled condition. However, the process level is not terminated. When the enclave level is terminated, any subsequent invocation creates a new enclave by using the same run-time options used in the creation of the first enclave. Language Environment does not delete any user routines that were loaded into the PreInit table. However, if, the first valid entry in the PreInit table is different than when the enclave was last initialized, the assembler user exit (CEEBXITA), HLL user exit (CEEBINT), and/or programmer default run-time options (CEEUOPT) used during the enclave re-initialization might be different. PreInit subroutine initialization uses these external references only when associated with the first valid entry in the PreInit table. Therefore, when using PreInit subroutine environments and you want consistent enclave initialization behavior across the stop semantics, you need to ensure the first valid entry in the PreInit table does not change, especially when it contains the aforementioned external references. (See “Stop semantics” on page 521.)
- Any subroutine that modifies external data cannot make assumptions about the initial state of that external data. The initial state of the external data is influenced by previous instances of the same subroutine and also by previous instances of any subroutine that caused enclave termination.

$(call\_sub\_addr)\quad$— invocation for subroutines by address
This invocation of CEEPIPI invokes a specified routine as a subroutine. The common run-time environment identified by $token$ is activated before the called routine is invoked; after the called routine returns, the environment is dormant.
The enclave is terminated when an unhandled condition is encountered or a STOP or EXIT statement (or an exit() function) is executed. (See "Stop semantics" on page 521 for more information.) However, the process level is maintained; only the enclave level terminates.

Syntax

\[
\text{CALL—CEEPIPI—(call_sub_addr—, routine_addr—, token—, \ldots)} \rightarrow \\
\text{parm_ptr—, sub_ret_code—, sub_reason_code—, sub_feedback_code—)} \rightarrow
\]

\textit{call_sub_addr} (input)
A fullword function code (integer value = 10) containing the call_sub request for a subroutine.

\textit{routine_addr} (input/output)
A doubleword containing the address of the routine that should be invoked. The first fullword contains the entry point address.

\textbf{Notes:}
1. If this is an XPLINK environment and the second fullword is zero, Preinitialization services will create a new function pointer to call the routine directly. The new function pointer will be returned in the second fullword.
2. If this is an XPLINK environment and the second fullword is a function pointer, the XPLINK subroutine is called directly. This fast path avoids the overhead of translating the routine address to the function pointer.

\textit{token} (input)
A fullword with the value of the token returned by (init_sub) or (init_sub_dp) when the common run-time environment is initialized.

The \textit{token} must identify a previously preinitialized environment that is not active at the time of the call. You must not alter the value of the token.

\textbf{Note:} If the token pointing to the previously preinitialized environment is a non-XPLINK environment and the subprogram to be invoked is XPLINK, then a return code of 40 will be returned because this is not valid.

\textit{parm_ptr} (input)
A parameter list pointer or 0 (zero) that is placed in register 1 when the routine is executed.

\text{C users are advised to follow the subroutine linkage convention for C — assembler ILC applications, as described in [OS C/C++ Programming Guide].}

\textit{sub_ret_code} (output)
The subroutine return code. If the enclave is terminated due to an unhandled condition or a STOP or EXIT statement (or an exit() function), this contains the enclave return code for termination.

\textit{sub_reason_code} (output)
The subroutine reason code. This is 0 for normal subroutine returns. If the enclave is terminated due to an unhandled condition or a STOP or EXIT statement (or an exit() function), this contains the enclave reason code for termination.

\textit{sub_feedback_code} (output)
The feedback code for enclave termination. This is the CEE000 feedback code
Preinitialization Services

for normal subroutine returns. If the enclave is terminated due to an unhandled condition or a STOP or EXIT statement (or an exit() function), this contains the enclave feedback code for termination.

**Return Codes:** A return code is provided in register 15 and can contain the following values:

- **0** The environment was activated and the routine called.
- **4** The function code is not valid.
- **8** CEEPIPI was called from a Language Environment-conforming HLL.
- **12** The indicated environment was initialized for main routines. No routine was executed.
- **16** The token is not valid.
- **28** The enclave was terminated but the process level persists.

This value indicates the enclave was terminated while the process was retained. This can occur due to a STOP or EXIT statement (or an exit() function) being issued or due to an unhandled condition. The sub_ret_code, sub_reason_code, and sub_feedback_code indicate this action.

- **40** The subprogram was an XPLINK program and the preinitialized environment is non-XPLINK. This is not valid.
- **41** Indicates the routine address could not be converted to a function descriptor.

**Usage Notes:**

- The enclave terminates if the subroutine issues a STOP or EXIT statement (or an exit() function), or if there is an unhandled condition. However, the process level is not terminated. When the enclave level is terminated, any subsequent invocation creates a new enclave using the same run-time options used in the creation of the first enclave. Language Environment does not delete any user routines that were loaded into the PreInit table.

However, if, the first valid entry in the PreInit table is different than when the enclave was last initialized, the assembler user exit (CEEBXITA), HLL user exit (CEEBINT), and/or programmer default run-time options (CEEUOPT) used during the enclave re-initialization might be different. PreInit subroutine initialization uses these external references only when associated with the first valid entry in the PreInit table. Therefore, when using PreInit subroutine environments and you want consistent enclave initialization behavior across the stop semantics, you need to ensure the first valid entry in the PreInit table does not change, especially when it contains the aforementioned external references. (See "Stop semantics" on page 521.)

- Any subroutine that modifies external data cannot make assumptions about the initial state of that external data. The initial state of the external data is influenced by previous instances of the same subroutine and also by previous instances of any subroutine that caused enclave termination.

- C subroutines that are not naturally reentrant and C++ subroutines can be invoked using call_sub_addr only in an XPLINK environment. In a non-XPLINK environment, they must be invoked using call_sub.

**(end_seq) — end a sequence of calls**

This invocation of CEEPIPI declares that a sequence of uninterrupted calls to subroutines by this driver program has finished.
end_seq (input)
A fullword function code (integer value = 8) containing the end_seq request.

token (input)
A fullword with the value of the token returned by (init_sub_dp) when the common run-time environment is initialized.

The token must identify a previously preinitialized environment that was prepared for multiple calls by the (start_seq) call.

Return Codes: A return code is provided in register 15 and can contain the following values:
0 The environment is no longer prepared for a sequence of calls.
4 The function code is not valid.
8 The indicated environment was already active; no action taken.
16 The token is not valid.
20 The token was not used in a start_seq call.

Usage Notes:
• (end_seq) can be used only in conjunction with a Language Environment environment initialized by an (init_sub_dp) function code. A return code of 4 is set for environments initialized by other than (init_sub_dp).
• Only (call_sub) or (call_sub_addr) invocations are allowed between the (start_seq) and (end_seq) calls.
• The driver program cannot cancel any STAE or ESPIE routines.
• This function can be called from an active environment if the Preinitialization environment indicated by token was created with the (init_sub_dp) function.

(start_seq) — start a sequence of calls
This invocation of CEEPIPI declares that a sequence of uninterrupted calls is made to a number of subroutines by this driven program to the same preinitialized environment. This minimizes the overhead between calls by performing as much activity as possible at the start of a sequence of calls.

start_seq (input)
A fullword function code (integer value = 7) containing the start_seq request.

token (input)
A fullword with the value of the token returned by (init_sub_dp) when the common run-time environment is initialized.

The token must identify a previously preinitialized environment for subroutines that are dormant at the time of the call.
Preinitialization Services

Return Codes: A return code is provided in register 15 and can contain the following values:

0  The environment was prepared for a sequence of calls.
4  The function code is not valid.
8  The indicated environment was already active; no action taken.
16 The token is not valid.
20 Sequence already started using token.

Usage Notes:

- (start_seq) can be used only in conjunction with a Language Environment environment initialized by (init_sub_dp) function code. A return code 4 is set for environments not initialized by (init_sub_dp).
- (start_seq) minimizes the overhead between calls by allowing Language Environment to perform as much activity as possible at the start of the sequence of calls.
- Only (call_sub) or (call_sub_addr) invocations are allowed between the (start_seq) and (end_seq) calls.
- The same token must be passed for all invocations of (call_sub) or (call_sub_addr) between the (start_seq) and (end_seq) function codes. You can vary the routine invoked.

(term) — terminate environment

This invocation of CEEPIPI terminates the environment identified by the value given in token. This service is used for terminating environments created for subroutines or main routines.

Syntax

```
CALL CEEPIPI (term, token, env_return_code)
```

term (input)
A fullword function code (integer value = 5) containing the termination request.

token (input)
A fullword with the value of the token of the environment to be terminated. This token is returned by a (init_main), (init_sub), or (init_sub_dp) request during the initialization call.

The token must identify a previously preinitialized environment that is dormant at the time of the call.

env_return_code (output)
A fullword integer which is set to the return code from the environment termination.

If the environment was initialized for a main routine or a subroutine, and the last (call_sub) or (call_sub_addr) issued stop semantics, the value of env_return_code is zero.

If the environment was initialized for a subroutine and the last (call_sub) or (call_sub_addr) did not terminate with stop semantics, env_return_code contains the same value as that in sub_ret_code from the last (call_sub) or (call_sub_addr).
Preinitialization Services

**Return Codes:** Upon return, register 15 contains a return code indicating the success or failure of this request and can contain the following values:

- **0** The environment was activated and termination was requested.
- **4** Non-valid function code.
- **8** CEEPIPI was called from a Language Environment-conforming routine.
- **16** The *token* is not valid.

**Usage Notes:**
- All resources obtained are released when the environment terminates.
- All routines loaded by Language Environment are deleted when the environment terminates.
- Subsequent references to *token* by preinitialization services result in an error indicating the token is not valid.

**(add_entry) — add an entry to the PreInit table**
This invocation of CEEPIPI adds an entry for the environment represented by *token* in the Language Environment-maintained table. If a routine entry address is not provided, the routine name is used to dynamically load the routine and add it to the PreInit table. The PreInit table index for the new entry is returned to the calling routine.

### Syntax

```
CALL CEEPIPI(--add_entry--,--token--,--routine_name--,----------)
ROUTINE_ENTRY--,--ceexptbl_index--
```

**add_entry (input)**
A fullword function code (integer value = 6) containing the add_entry request.

**token (input)**
A fullword with the value of the token associated with the environment that adds this new routine. This token is returned by a (init_main), (init_sub), or (init_sub_dp) request.

The *token* must identify a previously preinitialized environment that is dormant at the time of the call.

**routine_name (input)**
A character string of length 8, left-justified and padded right with blanks, containing the name of the routine. To indicate the absence of the name, this field should be blank. If *routine_entry* is zero, this is used as the load name.

**routine_entry (input/output)**
The routine entry address that is added to the PreInit table. If *routine_entry* is zero on input, *routine_name* is used as the load name. On output, *routine_entry* is set to the load address of *routine_name*.

The high-order bit of the entry_point address must be set to indicate the addressing mode for the routine. If the high-order bit is OFF, the routine is called in 24 bit addressing mode and the address must be a valid 24 bit address. If the high-order bit is ON, the routine is called in 31 bit addressing mode and the address must be a valid 31 bit address.
Preinitialization Services

**ceexptbl_index (output)**
The index to the Preinit table where this routine was added. If the return code is nonzero, this value is indeterminate. The index starts at zero.

**Note:** The environment that was preinitialized can be an XPLINK environment or a non-XPLINK environment. If the routine being added is an XPLINK routine, then the previously initialized environment must also be XPLINK.

**Return Codes:** Upon return, register 15 contains a return code indicating the success or failure of this request and can contain one of the following values:

- 0  The routine was added to the Preinit table.
- 4  Non-valid function code.
- 8  CEEPIPI was called from a Language Environment-conforming routine.
- 12 The routine did not contain a valid Language Environment entry prolog. Insure that the routine was compiled with a current Language Environment enabled compiler. The Preinit table was not updated. The routine_entry is set to the address of the loaded routine.
- 16 The token is not valid.
- 20 The routine_name contains only blanks and the routine_entry was zero. The Preinit table was not updated.
- 24 The routine_name was not found or there was a load failure; the Preinit table was not updated.
- 28 The Preinit table is full. No routine was added to the table, nor was any routine loaded by Language Environment.
- 32 An unhandled error condition was encountered. This error is a result of a program interrupt or other abend that occurred that prevented the preinitialization services from completing.
- 38 Non-valid entry: A non-XPLINK sub-environment was preinitialized and the program that was being added is an XPLINK program.
- 42 Non-valid entry: The routine_entry had the high order bit off indicating this routine is a 24 bit addressing mode routine but the environment is an XPLINK 31 bit environment. This is not valid.
- 44 The routine to be added contains a language that is not supported on the z/OS.e operating system.

**Usage Notes:**
- The PreInit table is built using the macros described in this chapter. Therefore, its size is under the control of your application, not Language Environment.
- None of the routines in the PreInit table can be nested routines. All routines must be external routines.
- Language Environment uses the high-order bit of the entry address to determine what AMODE to use when calling the routine. If the routine_entry is zero, and the routine_name is supplied, Language Environment uses the AMODE returned by the system loader. If the routine_entry is supplied, you must provide the AMODE in the high-order bit of the address.
- An add_entry of an XPLINK program into a non-XPLINK preinitialized sub-environment will be not valid. If the environment is non-XPLINK, then the subprogram added with the add_entry function must also be non-XPLINK. However, you can do an add_entry of a main XPLINK program into a non-XPLINK environment. When a call_main is done with this scenario the environment will switch to XPLINK in order to allow the program to run.

**(delete_entry) — delete an entry from the PreInit table**
This function deletes an entry from the PreInit table. The entry is then available for subsequent (add_entry) functions.
Syntax

CALL CEEPIPI (delete_entry, token, ceexptbl_index)

delete_entry (input)
fullword function code (integer value = 11) containing the delete_entry request

token (input)
a fullword with the value of the token of the environment. This is the token returned by a (init_main), (init_sub), or (init_sub_dp) request.

ceexptbl_index (input)
the index into the PreInit table of the entry to delete.

Return Codes: Upon return, R15 contains a return code indicating the success or failure of this request and may contain the following values:

0  The routine was deleted from the PreInit table
4  The function code is not valid.
8  CEEPIPI was called from an active environment. No entries were deleted from the PreInit table.
16  The token is not valid
20  The PreInit table entry indicated by ceexptbl_index was empty.
24  The index passed is outside the range of the table.
28  The system request to delete the routine failed; the routine was not deleted from the PreInit table.

Usage Notes:
• The token must identify a previously preinitialized environment that is dormant at the time of the call.
• If the routine indicated by ceexptbl_index had been loaded by CEEPIPI, it will be deleted.
• (delete_entry) no longer issues return code 12 (the environment indicated by token was not created with a (init_main) request; the routine was not deleted from the PreInit table).

(identify_entry) — identify an entry in the PreInit table
The invocation of this routine identifies the language of the entry point for a routine in the PreInit table.

Syntax

CALL CEEPIPI (identify_entry, token, ceexptbl_index, programming_language)

identify_entry (input)
A fullword containing the identify_entry function code (integer value=13).

token (input)
A fullword with the value of the token of the environment. This is the token returned by a (init_main) or (init_sub) or (init_sub_dp) request.
Preinitialization Services

`ceexptbl_index (input)`
A fullword containing the index in the PreInit table of the entry to identify the programming language.

`programming language (output)`
A fullword with one of the following possible values:

<table>
<thead>
<tr>
<th>Value</th>
<th>Language</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>C/C++</td>
</tr>
<tr>
<td>5</td>
<td>COBOL</td>
</tr>
<tr>
<td>10</td>
<td>PL/I</td>
</tr>
<tr>
<td>11</td>
<td>Enterprise PL/I for z/OS and OS/390, VisualAge PL/I for OS/390</td>
</tr>
<tr>
<td>15</td>
<td>Language Environment-enabled assembler</td>
</tr>
<tr>
<td>16</td>
<td>PL/X</td>
</tr>
</tbody>
</table>

`Return Codes:` Upon return, register 15 contains a return code indicating the success or failure of this request and can contain the following values:

<table>
<thead>
<tr>
<th>Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>The programming language has been returned.</td>
</tr>
<tr>
<td>4</td>
<td>Non-valid function code.</td>
</tr>
<tr>
<td>8</td>
<td>CEEPIPI was called from an active environment.</td>
</tr>
<tr>
<td>16</td>
<td>The token is not valid.</td>
</tr>
<tr>
<td>20</td>
<td>The PreInit table entry indicated by <code>ceexptbl_index</code> was empty.</td>
</tr>
<tr>
<td>24</td>
<td>The index passed is outside the range of the table.</td>
</tr>
</tbody>
</table>

`Usage Notes:`

- The token must identify a previously preinitialized environment that is dormant at the time of the call and was established with the (init_main) or (init_sub) or (init_sub_dp) request.
- The `programming language` can be used by the driver to determine what format the parameter list must be in the PreInit table in cases where the language of the entry is not known.
- When a PreInit table entry contains multiple languages, `programming language` is the language of the entry point for the entry.

`(identify_environment) — identify the environment in the PreInit table`
This invocation of CEEPIPI identifies the environment that was preinitialized.

**Syntax**

```
CALL CEEPIPI (identify_environment, token, pipi_environment)
```

`identify_environment (input)`
A fullword containing the `identify_environment` function code (integer value=15).

`token (input)`
A fullword with the value of the token of the environment. This is the token returned by a (init_main) or (init_sub) or (init_sub_dp) request.

`pipi_environment (output)`
A fullword (32 Bit) mask value will be returned indicating the following:

<table>
<thead>
<tr>
<th>Mask Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>X'80000000'</td>
<td>PreInit main environment is initialized</td>
</tr>
<tr>
<td>X'40000000'</td>
<td>PreInit enclave is initialized</td>
</tr>
</tbody>
</table>
Preinitialization Services

Table 65. pipi_environment mask values (continued)

<table>
<thead>
<tr>
<th>pipi_environment</th>
<th>Mask Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ceepipi_dp_environment</td>
<td>X'20000000'</td>
<td>PreInit sub dp environment initialized</td>
</tr>
<tr>
<td>ceepipi_dp_seq_of_calls_active</td>
<td>X'10000000'</td>
<td>PreInit seq call function active</td>
</tr>
<tr>
<td>ceepipi_dp_exits_established</td>
<td>X'08000000'</td>
<td>PreInit sub dp exits set</td>
</tr>
<tr>
<td>ceepipi_sir_unregistered</td>
<td>X'04000000'</td>
<td>PreInit sir registered</td>
</tr>
<tr>
<td>ceepipi_sub_environment</td>
<td>X'02000000'</td>
<td>PreInit sub environment initialized</td>
</tr>
<tr>
<td>ceepipi_XPLINK_environment</td>
<td>X'01000000'</td>
<td>PreInit XPLINK environment initialized</td>
</tr>
</tbody>
</table>

**Return Codes:** Upon return, register 15 contains a return code indicating the success or failure of this request and can contain the following values:

- **0**: The Preinitialization environment mask has been returned.
- **4**: Non-valid function code.
- **8**: CEEPIPI was called from an active environment.
- **16**: The token is not valid.

(identify_attributes) — identify the program attributes in the PreInit table

This invocation of CEEPIPI identifies the program attributes of a program in the PreInit table.

**Syntax**

```
CALL CEEPIPI (identify_attributes, token,
              ceexptbl_index(input), program_attributes)
```

**identify_attributes (input)**

A fullword containing the identify_attributes function code (integer value=16).

**token (input)**

A fullword with the value of the token of the environment. This is the token returned by a (init_main) or (init_sub) or (init_sub_dp) request.

**ceexptbl_index (input)**

A fullword containing the index in the PreInit table of the entry to identify the programming attributes.

**program_attributes (output)**

A fullword (32-bit) mask value will be returned indicating the following:

Table 66. program_attributes mask values

Service routines

Under Language Environment, you can specify several service routines to execute a main routine or subroutine in the preinitialized environment. To use the routines, specify a list of addresses of the routines in a service routine vector as shown in Figure 171.

```
SERV_RTNS  Count
User Word
@WorkArea
@LOAD
@DELETE
@GETSTORE
@FREESTORE
@EXCEPRTN
reserved
@MSGRTN
```

**Figure 171. Format of Service Routine Vector**

The service routine vector is composed of a list of fullword addresses of routines that are used instead of Language Environment service routines. The list of addresses is preceded by the number of the addresses in the list, as specified in the count field of the vector. The service_rtns parameter that you specify in calls to (init_main) and (init_sub) contains the address of the vector itself. If this pointer is specified as zero (0), Language Environment routines are used instead of the service routines shown in Figure 171.

The @GETSTORE and @FREESTORE service routines must be specified together; if one is zero, the other is automatically ignored. The same is true for the @LOAD and @DELETE service routines. If you specify the @GETSTORE and @FREESTORE service routines, you do not have to specify the @LOAD and @DELETE service routines and vice-versa.

When replacing only the storage management routines without the program management routines, the user must be aware that they may not be accounting for all the storage obtained on behalf of the application. Contents management obtains storage for the load module being loaded. This storage will not be managed by the user storage management routines.
The service routines may be AMODE(31) / RMODE(ANY) if the application has no AMODE(24) programs. Otherwise the service routines must be AMODE(ANY) / RMODE(24).

**Count**
A fullword binary number representing the number of fullwords that follow. The count does not include itself. In Figure 171 on page 542, the count is 9. For each vector slot, a zero represents the absence of the routine, a nonzero represents the presence of a routine.

**User Word**
A fullword that is passed to the service routines. The user word is provided as a means for your routine to communicate to the service routines.

**@WorkArea**
An address of a work area of at least 256 bytes that is doubleword aligned. The first word of the area contains the length of the area provided.

This parameter is required if service routines are present in the service routine vector.

This length field must be initialized each time you bring up a new PreInit environment.

**@LOAD**
This routine loads named routines for application management. The parameter that is passed contains the following:

- **Name_addr** The fullword address of the name of the module to load (input parameter).
- **Name_length** A fixed binary(31) length of the module name (input parameter).
- **User_word** A fullword user field (input parameter).
- **Load_point** Either zero (0), or the address where the @LOAD routine is to store the load point address of the loaded routine (input and output parameter).
- **Entry_point** The fullword entry point address of the loaded routine (output parameter).
- **Module_size** The fixed binary(31) size of the module that was loaded (output parameter).
- **Return code** The fullword return code from load (output).
- **Reason code** The fullword reason code from load (output).

The return and reason codes are listed in Table 67.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>

<td>Unsuccessful — module loaded above the line when in AMODE(24)</td>
</tr>
<tr>
<td>8</td>
<td>4</td>
<td>Unsuccessful — load failed</td>
</tr>
<tr>
<td>16</td>
<td>4</td>
<td>Unsuccessful — uncorrectable error occurred</td>
</tr>
</tbody>
</table>

Table 67. Return and Reason Codes
Preinitialization Services

@DELETE
This routine deletes routines for application management. The parameter that is passed contains the following:

**Name_addr**
The fullword address of the module name to be deleted (input parameter).

**Name_length**
A fixed binary(31) length of module name (input parameter).

**User_word**
A fullword user field (input parameter).

**Rsvd_word**
A fullword reserved for future use (input parameter); must be zero.

**Return code**
The return code from delete service (output).

**Reason code**
The reason code from delete service (output).

The return and reason codes are listed in Table 68.

<table>
<thead>
<tr>
<th>Return Code</th>
<th>Reason Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Successful</td>
</tr>

<td>8</td>
<td>4</td>
<td>Unsuccessful — delete failed</td>
</tr>
<tr>
<td>16</td>
<td>4</td>
<td>Unsuccessful — uncorrectable error occurred</td>
</tr>
</tbody>
</table>

@GETSTORE
This routine allocates storage on behalf of the storage manager. This routine can rely on the caller to provide a save area, which can be the @Workarea. The parameter list that is passed contains the following:

**Amount**
A fixed binary(31) amount of storage requested (input parameter).

**Subpool_no**
A fixed binary(31) subpool number 0-127 (input parameter). Language Environment allocates storage from the process-level storage pools.

**User_word**
A fullword user field (input parameter).

**Flags**
A fullword flag area (input parameter).

Bit zero in Flags is ON if the storage is required below the 16M line. The remaining bits are reserved for future use and must be zero. Bit zero in Flags is OFF if the storage required can be allocated anywhere.

**Stg_address**
The fullword address of the storage obtained or zero (output parameter).

**Obtained**
A fixed binary(31) number of bytes obtained (output parameter).

**Return code**
The return code from @GETSTORE service (output parameter).
Reason code
The reason code from the @GETSTORE service (output parameter).

The return and reason codes are listed in Table 69.

Table 69. Return and Reason Codes

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Successful</td>
</tr>
<tr>
<td>16</td>
<td>0</td>
<td>Unsuccessful — uncorrectable error occurred</td>
</tr>
</tbody>
</table>

@FREESTORE
This routine frees storage on behalf of the storage manager. The parameter list passed contains the following:

Amount
The fixed binary(31) amount of storage to free (input parameter).

Subpool_no
The fixed binary(31) subpool number 0-127 (input parameter). Language Environment allocates storage from the process-level storage pools.

User word
A fullword user field (input parameter).

Stg_address
The fullword address of the storage to free (input parameter).

Return code
The return code from the @FREESTORE service (output).

Reason code
The reason code from the @FREESTORE service (output).

The return and reason codes are listed in Table 70.

Table 70. Return and Reason Codes

<table>

<td>0</td>
<td>Successful</td>
</tr>
<tr>
<td>16</td>
<td>0</td>
<td>Unsuccessful — uncorrectable error occurred</td>
</tr>
</tbody>
</table>

@EXCEPRTN
This routine traps program interruptions and abends for condition management. The parameter list passed contains the following:

Handler_addr
During an initialization call, this parameter contains the address of the CEL condition handler. During a termination call, this parameter contains a pointer to a fullword field containing zeroes.

Environment_token
A fullword Recovery Environment token (input). (Note that this token is different from the Preinitialization environment token used with CEEPIPI calls.)

User_word
A fullword user field (input parameter)
Preinitialization Services

**Abend_flags**
A fullword flag area containing abend flags (input)

**Check_flags**
A fullword flag area containing program check flags (input)

**Return code**
The return code from the @EXCEPRTN service (output).

**Reason code**
The reason code from the @EXCEPRTN service (output).

The exception router is responsible for trapping and routing exceptions. These are the services typically obtained via the ESTAE and ESPIE macros.

During initialization, if the TRAP option is in effect the common library puts the address of the Language Environment exception in the first field of the above parameter list, and sets the environment token field to a value that will be passed on to the exception handler. It also sets abend and check flags as appropriate, and then calls your exception router to establish an exception handler.

The meaning of the bits in the abend flags are given by the following declare:

```plaintext
dcl abendflags,  
  system,  
  abends bit(1), /* control for system abends desired */  
  rsv1 bit(15), /* reserved */  
  user,  
  abends bit(1), /* control for user abends desired */  
  rsv2 bit(15); /* reserved */
```

The meaning of the bits in the check flags is given by the following declare:

```plaintext
dcl checkflags,  
  type,  
  reserved3 bit(1),  
  operation bit(1),  
  privileged_operation bit(1),  
  execute bit(1),  
  protection bit(1),  
  addressing bit(1),  
  specification bit(1),  
  data bit(1),  
  fixed_overflow bit(1),  
  fixed_divide bit(1),  
  decimal_overflow bit(1),  
  decimal_divide bit(1),  
  exponent_overflow bit(1),  
  exponent_underflow bit(1),  
  significance bit(1),  
  float_divide bit(1),  
  reserved4 bit(16);
```

The return and reason codes that the exception router must use are listed in Table 71.

**Table 71. Return and Reason Codes**

</tr>
</tbody>
</table>

When an exception occurs, the exception router must determine if the established exception handler is interested in the exception (by examining abend and check flags). If the exception handler is not interested in the exception, the exception router must treat the program as in error, but can assume the environment for the thread to be functional and reusable. If the exception handler is interested in the exception, the exception router must invoke the exception handler, passing the parameters listed in Table 72.

Table 72. Parameters for EXCEPRTN

</tr>
<tr>
<td>0</td>
<td>4</td>
<td>Continue with the exception.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Percolate the exception taking whatever action would have been taken had it not been handled at all. In this case, the environment for the thread is probably unreliable and not reusable. A forced termination is suggested.</td>
</tr>
<tr>
<td>4</td>
<td>0</td>
<td>Resume execution using the updated SDWA.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>The invoked exception handler will have already used the SETRP RTM macro to set the SDWA for correct resumption.</td>
</tr>
</tbody>
</table>

During termination, the exception router is invoked with the exception handler address (first parameter) set to zero to de-establish the exit (if it was established during initialization).

When a nested enclave is created, the Language Environment exception handler calls the exception router to establish another exception handler exit, and then makes a call to de-establish it when the nested enclave terminates. If an exception occurs while the second exit is active, special processing is
Preinitialization Services

performed. Depending on what this second exception is, either the first exception will not be retried, or processing will continue on the first exception by requesting retry for the second exception.

If the Language Environment exception handler determines that execution should resume for an exception, it will set the SDWA with SETRP and return with return/reason codes 4/0. Execution will resume in library code or in user code, depending on what the exception was.

The exception router must be capable of restoring all the registers from the SDWA when control is given to the retry routine. The ESPIE and ESTAE services are capable of accomplishing this.

In using the exception router service:
- The exception router should not invoke the Language Environment exception handler if active I/O has been halted and is not restorable.
- This service requires an XA or ESA environment.

If an exception occurs while the exception handler is in control before another exception handler exit has been stacked, the exception router should assume that the exception could not be handled and that the environment for the program (thread) is damaged. In this case, the exception router should force termination of the preinitialized environment.

@MSGRTN
This routine allows error messages to be processed by the caller of the application.

If the message pointer is zero, your message routine is expected to return the size of the line to which messages are written (in the line_length field). This allows messages to be formatted correctly — that is, broken at places such as blanks.

Message
A pointer to the first byte of text that is printed, or zero (input parameter).

Msg_len
The fixed binary(31) length of the message (input parameter).

User word
A fullword user field (input parameter).

Line_length
The fixed binary(31) size of the output line length. This is used when Message is zero (output parameter).

Return and reason codes
Two fullwords containing the return and reason codes listed in Table 74 (output parameters).

Table 74. Return and Reason Codes

An example program invocation of CEEPIPI

Figure 172 on page 550 is a sample of a PreInit assembler driver program. This assembler program called ASMPIPI invokes CEEPIPI to:

• Initialize a subroutine environment under Language Environment
• Load and call a reentrant HLL subroutine
• Terminate the Language Environment environment

Following the assembler program are examples of the program HLLPIPI written in C, COBOL, and PL/I. HLLPIPI is called by an assembler program, ASMPIPI. ASMPIPI uses the Language Environment preinitialized program subroutine call interface. You can use the assembler program to call the HLL versions of HLLPIPI.
Function: CEEPIPI - Initialize the Preinitialization environment, call a Preinitialization HLL program, and terminate the environment.

1. Call CEEPIPI to initialize a subroutine environment under LE.
2. Call CEEPIPI to load and call a reentrant HLL subroutine.
3. Call CEEPIPI to terminate the LE Preinitialization environment.

Note: ASMPIPI is not reentrant.

Figure 172. Assembler Driver That Creates a Preinitialized Environment (Part 1 of 3)

Chapter 31. Using nested enclaves

An enclave is a logical run-time structure that supports the execution of a collection of routines (see Chapter 13, “Program Management Model,” on page 159 for a detailed description of Language Environment enclaves).

Language Environment explicitly supports the execution of a single enclave within a Language Environment process. However, by using the system services and language constructs described in this chapter, you can create an additional, or nested, enclave and initiate its execution within the same process.

The enclave that issues a call to system services or language constructs to create a nested enclave is called the parent enclave. The nested enclave that is created is called the child enclave. The child must be a main routine; a link to a subroutine by commands and language constructs is not supported under Language Environment.

If a process contains nested enclaves, none or only one enclave can be running with POSIX(ON).

Understanding the basics

In Language Environment, you can use the following methods to create a child enclave:

• Under CICS, the EXEC CICS LINK and EXEC CICS XCTL commands (see CICS Application Programming Guide for more information about these commands).
• Under z/OS, the SVC LINK macro
• Under z/OS, the C sys(tem)() function (see z/OS C/C++ Programming Guide for more information about sys(tem)()).
• Under z/OS, the PL/I FETCH and CALL to any of the following PL/I routines with PROC OPTIONS(MAIN) specified:
  – VisualAge PL/I
  – PL/I for MVS & VM
  – OS PL/I Version 2
  – OS PL/I Version 1 Release 5.1
  – Relinked OS PL/I Version 1 Release 3.0 – 5.1

Such a routine, called a fetchable main in this book, can only be introduced by a FETCH and CALL from a PL/I routine. COBOL cannot dynamically call a PL/I main and C cannot issue a fetch() against a PL/I main. In addition, a fetchable main cannot be dynamically loaded using the CEELOAD macro.

The routine performing the FETCH and CALL must be compiled with the VisualAge PL/I or the PL/I for MVS & VM compiler, or be a relinked OS PL/I routine.

If the target routine of any of these commands is not written in a Language Environment-conforming HLL or Language Environment-conforming assembler, no nested enclave is created.

XPLINK considerations

A nested enclave situation where the parent enclave is running in an XPLINK(OFF) environment and the child enclave requires XPLINK(ON) is not supported. A parent enclave running XPLINK(ON) will support a nested child enclave of either XPLINK(ON) or XPLINK(OFF). In the latter case, the application in the child enclave
Using Nested Enclaves

will go through compatibility glue code when calling the C RTL (that is, the child enclave will run with an environment with the XPLINK run-time option forced ON).

COBOL considerations

In a non-CICS environment, OS/VS COBOL programs are supported in a single enclave only.

PL/I considerations

PL/I MTF is supported in the initial enclave only. If PL/I MTF is found in a nested enclave, Language Environment diagnoses it as an error. If a PL/I MTF application contains nested enclaves, the initial enclave must contain a single task. Violation of this rule is not diagnosed and is likely to cause unpredictable results.

Determining the behavior of child enclaves

If you want to create a child enclave, you need to consider the following factors:

- The language of the main routine in the child enclave
- The sources from which each type of child enclave gets run-time options
- The default condition handling behavior of each type of child enclave
- The setting of the TRAP run-time option in the parent and the child enclave

All of these interrelated factors affect the behavior, particularly the condition handling, of the created enclave. The sections that follow describe how the child enclaves created by each method (EXEC CICS LINK, EXEC CICS XCTL, SVC LINK, C startup() function, and PL/I FETCH and CALL of a fetchable main) will behave.

Creating child enclaves with EXEC CICS LINK or EXEC CICS XCTL

If your C, C++, COBOL, or PL/I application uses EXEC CICS commands, you must also link-edit the EXEC CICS interface stub, DFHELII, with your application. To be link-edited with your application, DFHELII must be available in the link-edit SYSLIB concatenation.

See [CICS Application Programming Guide](#) for more information about the EXEC CICS LINK and EXEC CICS XCTL commands.

How run-time options affect child enclaves

The child enclave gets its run-time options from one of the sources discussed in ["Specifying Run-Time Options under CICS" on page 437](#). The run-time options are completely independent of the creating enclave, and can be set on an enclave-by-enclave basis.

Some of the methods for setting run-time options might slow down your transaction. Follow these suggestions to improve performance:

- If you need to specify options in CEEUOPT specify only those options that are different from system defaults.
- Before putting transactions into production, request a storage report (using the RPTSTG run-time option) to minimize the number of GETMAINs and FREEMAINs required by the transactions.
- Ensure that VS COBOL II transactions are not link-edited with IGZETUN and IGZEOPT, which are no longer supported and which cause an informational message to be logged. Logging this message for every transaction inhibits system performance. The sample user condition handler CEEWUCHA can be
Creating child enclaves

used to prevent this informational message from being logged. See [Enterprise COBOL for z/OS Migration Guide](#) for more information.

**How conditions arising in child enclaves are handled**

This section describes the default condition handling for child enclaves created by EXEC CICS LINK or EXEC CICS XCTL.

Condition handling varies depending on the source of the condition, and whether an EXEC CICS HANDLE ABEND is active:

- If a Language Environment or CEEBXITA-initiated (generated by setting the CEEAUE_ABND field of CEEBXITA) abend occurs, the CICS thread is terminated. This occurs even if a CICS HANDLE ABEND is active, because CICS HANDLE ABEND does not gain control in the event of a Language Environment abend.

- If a software condition of severity 2 or greater occurs, Language Environment condition handling takes place. If the condition remains unhandled, the problem is not percolated to the parent enclave. The CICS thread is terminated with an abend. These actions take place even if a CICS HANDLE ABEND is active, because CICS HANDLE ABEND does not gain control in the event of a Language Environment software condition.

- If a user abend or program check occurs, the following actions take place:
  - If no EXEC CICS HANDLE ABEND is active, and TRAP(ON) is set in the child enclave, Language Environment condition handling takes place. If the abend or program check remains unhandled, the problem is not propagated to the parent enclave. The CICS thread is terminated with an abend.
  - An active EXEC CICS HANDLE ABEND overrides the setting of TRAP. The action defined by the EXEC CICS HANDLE ABEND takes place.

**Creating child enclaves by calling a second main program**

The behavior of a child enclave created by calling a second main program is determined by the language of its main or initializing routine: C, C++, COBOL, Fortran, PL/I, or Language Environment-conforming assembler (generated by use of the CEEENTRY and associated macros).

**How run-time options affect child enclaves**

Run-time options will be processed in the normal manner for enclaves created because of a call to a second main, that is, programmer defaults present in the load module will be merged, options in the command line equivalent will also be processed, as will options passed by the assembler user exit if present.

**How conditions arising in child enclaves are handled**

The command-line equivalent is determined in the same manner as for a SVC LINK.

**Creating child enclaves using SVC LINK**

The behavior of a child enclave created by an SVC LINK is determined by the language of its main routine: C, C++, COBOL, Fortran, PL/I, or Language Environment-conforming assembler (generated by use of the CEEENTRY and associated macros).

When issuing a LINK to a routine, the high-order bit must be set on for the last word of the parameter list. To do this, set VL=1 on the LINK assembler macro.
Using Nested Enclaves

How run-time options affect child enclaves
Child enclaves created by an SVC LINK get run-time options differently, depending on the language that the main routine of the child enclave is written in.

Child enclave has a C, C++, Fortran, PL/I, or Language Environment-conforming assembler main routine: If the main routine of the child enclave is written in C, C++, Fortran, PL/I, or in Language Environment-conforming assembler, the child enclave gets its run-time options through a merge from the usual sources (see Chapter 9, “Using Run-Time Options,” on page 117 for more information). Therefore, you can set run-time options on an enclave-by-enclave basis.

Child enclave has a COBOL main program: If the main program of the child enclave is written in COBOL, the child enclave inherits the run-time options of the creating enclave. Therefore, you cannot set run-time options on an enclave-by-enclave basis.

How conditions arising in child enclaves are handled
If a Language Environment or CEEBXITA-initiated (generated by setting the CEEAU_E_ABND field of CEEBXITA) abend occurs in a child enclave created by SVC LINK, regardless of the language of its main, the entire process is terminated.

Condition handling in child enclaves created by SVC LINK varies, depending on the language of the child’s main routine, the setting of the TRAP run-time option in the parent and child enclaves, and the type of condition. Refer to one of the following tables to see what happens when a condition remains unhandled in a child enclave.

Table 75. Handling Conditions in Child Enclaves

<table>
<thead>
<tr>
<th>If the Child Enclave Was Created By:</th>
<th>See:</th>
</tr>
</thead>
<tbody>
<tr>
<td>An SVC LINK and has a C, C++, or Language Environment-conforming assembler main routine</td>
<td>Table 76</td>
</tr>
<tr>
<td>An SVC LINK and has a COBOL main program</td>
<td>Table 77 on page 559</td>
</tr>
<tr>
<td>An SVC LINK and has a Fortran or PL/I main routine</td>
<td>Table 78 on page 559</td>
</tr>
</tbody>
</table>

You should always run your applications with TRAP(ON) or your results might be unpredictable.

Child enclave has a C, C++, or Language Environment-conforming assembler main routine: Table 76 shows the unhandled condition behavior.

Table 76. Unhandled Condition Behavior in a C, C++, or Assembler Child Enclave

<table>
<thead>
<tr>
<th>Condition</th>
<th>Parent Enclave TRAP(ON)</th>
<th>Parent Enclave TRAP(ON)</th>

### Creating child enclaves using the C system() function

Child enclaves created by the C `system()` function get run-time options through a merge from the usual sources (see Chapter 9, “Using Run-Time Options,” on page 117 for more information). Therefore, you can set run-time options on an enclave-by-enclave basis. See z/OS C/C++ Run-Time Library Reference for information on the `system()` function when running with POSIX(ON).

When you perform a `system()` function to a COBOL program, in the form:

```c
system("PGM=program_name,PARM='...'")
```

the run-time options specified in the PARM= portion of the `system()` function are ignored. However, run-time options are merged from CEEDOPT, CEEUOPT, and the CEEAUOE_A_OPTIONS from the assembler user exit.

### z/OS UNIX considerations

To create a nested enclave under z/OS UNIX, you must either:
- Be running with POSIX(OFF) and issue `system()`, or
- Be running with POSIX(ON) and have set the environment variables to signal that you want to establish a nested enclave. You can use the `__POSIX_SYSTEM` environment variable to cause a `system()` to establish a nested enclave instead of performing a `spawn()`. `__POSIX_SYSTEM` can be set to `N0`, `No`, or `no`.

The `system()` function is not thread safe. It cannot be called simultaneously from more than one thread. A multi-threaded application must ensure that no more than one `system()` call is ever outstanding from the various threads. If this restriction is violated, unpredictable results may occur. In a multiple enclave environment, the first enclave must be running with POSIX(ON) and all other nested enclaves must be running with POSIX(OFF).

### How conditions arising in child enclaves are handled

If a Language Environment- or CEEBXITA-initiated (generated by setting the CEEAUOE_ABND field of CEEBXITA) abend occurs in a child enclave created by a call to `system()`, the entire process is terminated.

---

**Creating child enclaves containing a PL/I fetchable main**

Fetch and call considerations of PL/I fetchable mains are discussed in “Special fetch and call considerations” on page 562.

**How run-time options affect child enclaves**

Child enclaves created when you issue a FETCH and CALL of a fetchable main get run-time options through a merge from the usual sources (see Chapter 9, “Using Run-Time Options,” on page 117 for more information). Therefore, you can set run-time options on an enclave-by-enclave basis.

**How conditions arising in child enclaves are handled**

If a Language Environment or CEEBXITA-initiated (generated by setting the CEEAUE_ABND field of CEEBXITA) abend occurs in a child enclave that contains a fetchable main, the entire process is terminated.

Depending on what the settings of the TRAP run-time option are in the parent and child enclave, the following might cause the child enclave to terminate:

- Unhandled user abend
- Unhandled program check

Table 80 on page 562 describes the unhandled condition behavior in a child enclave.
Using Nested Enclaves

</tr>
</tbody>
</table>

Special fetch and call considerations
You should not recursively fetch and call the fetchable main from within the child enclave; results are unpredictable if you do.

The load module that is the target of the FETCH and CALL is reentrant if all routines in the load module are reentrant. (See Chapter 11, “Making Your Application Reentrant,” on page 139 for more information on reentrancy.)

Language Environment relies on the underlying operating system for the management of load module attributes. In general, multiple calls of the same load module are supported for load modules that are any of the following:

- Reentrant
  It is recommended that your target load module be reentrant.
- Nonreentrant but serially reusable
  You should ensure that the main procedure of a nonreentrant but serially reusable load module is self-initializing. Results are unpredictable otherwise.
- Nonreentrant and non-serially reusable
  If a nonreentrant and non-serially reusable load module is called multiple times, each new call brings in a fresh copy of the load module. That is, there are two copies of the load module in storage: one from FETCH and one from CALL. Even though there are two copies of the load module in storage, you need only one PL/I RELEASE statement because upon return from the created enclave the load module loaded by CALL is deleted by the operating system. You need only release the load module loaded by FETCH.

Other nested enclave considerations
The following sections contain other information you might need to know when creating nested enclaves. The topics include:

- The string that CEE3PRM returns for each type of child enclave (see z/OS Language Environment Programming Reference for more information about the CEE3PRM callable service)
The return and reason codes that are returned on termination of the child enclave

- How the assembler user exit handles nested enclaves
- Whether the message file is closed on return from a child enclave
- z/OS UNIX considerations
- AMODE considerations

What the enclave returns from CEE3PRM

CEE3PRM returns to the calling routine the user parameter string that was specified at program invocation. Only program arguments are returned.

See Table 81 to determine whether a user parameter string was passed to your routine, and where the user parameter string is found. This depends on the method you used to create the child enclave, the language of the routine in the child enclave, and the PLIST, TARGET, or SYSTEM setting of the main routine in the child enclave. If a user parameter string was passed to your routine, the user parameter string is extracted from the command-line equivalent for your routine (shown in Table 82 on page 564) and returned to you.

Note: Under CICS, CEE3PRM always returns a blank string.

</tbody>
</table>

If Table 81 on page 563 indicates that a parameter string was passed to your routine at invocation, the string is extracted from the command-line equivalent listed in the right-hand column of Table 82. The command-line equivalent depends on the language of your routine and the run-time options specified for it.

Finding the return and reason code from the enclave

The following list tells where to look for the return and reason codes that are returned to the parent enclave when a child enclaves terminates:

- **EXEC CICS LINK or EXEC CICS XCTL**
  
  If the CICS thread was not terminated, the return code is placed in the optional RESP2 field of EXEC CICS LINK or EXEC CICS XCTL. The reason code is discarded.

- **SVC LINK to a child enclave with a main routine written in any Language Environment-conforming language**
  
  If the process was not terminated, the return code is reported in R15. (See “Managing return codes in Language Environment” on page 151 for more information.) The reason code is discarded.

- **C’s **function
  
  If the target command or program of system() cannot be started, “-1” is returned as the function value of system(). Otherwise, the return code of the child enclave is reported as the function value of system(), and the reason code is discarded. (See z/OS C/C++ Programming Guide for more information about the system() function.)

- **FETCH and CALL of a fetchable main**
  
  Normally, the enclave return code and reason code are discarded when control returns to a parent enclave from a child enclave. However, in the parent enclave, you can specify the OPTIONS(ASSEMBLER RETCODE) option of the entry constant for the main procedure of the child enclave. This causes the enclave return code of the child enclave to be saved in R15 as the PL/I return code. You can then interrogate that value by using the PLIRETV built-in function in the parent enclave.

Assembler user exit

An assembler user exit (CEEBXITA) is driven for enclave initialization and enclave termination regardless of whether the enclave is the first enclave created in the process or a nested enclave. The assembler user exit differentiates between first and nested enclave initialization.

Message file

The message file is not closed when control returns from a child enclave.

COBOL multithreading considerations

When COBOL is run in a multithread environment or a PL/I multitasking environment, a nested enclave cannot be created. An attempt to create a nested enclave will result in a severity 3 condition being generated.

z/OS UNIX considerations

The following restrictions must be considered when running with POSIX(OFF) or POSIX(ON):

- In Language Environment a process can have only one enclave that is running with POSIX(ON), and that enclave must be the first enclave if that process contains multiple enclaves. All nested enclaves must be enclaves with POSIX(OFF).
- C fork() and exec() can be issued only from a single-thread enclave.
Using Nested Enclaves

Any violations of the above restrictions result in a severity 3 condition being generated.

AMODE considerations

In a non-CICS environment ALL31 should have the same setting for all enclaves within a process. You cannot invoke a nested enclave that requires ALL31(OFF) from an enclave running with ALL31(ON).
Part 6. Appendixes
Appendix A. Prelinking an Application

This appendix describes how to prelink your programs under Language Environment. Unless otherwise indicated, the prelinking process applies to C, C++, COBOL and VisualAge PL/I.

The Language Environment prelinker performs mapping of names, manages writable static areas, collects initialization information, and combines the object modules that form an application into a single object module that can be link-edited or loaded for execution.

Note: The prelink step in creating an executable program can be eliminated. The binder is able to directly receive the output of the C, C++, COBOL, and VisualAge PL/I compilers, thus eliminating the requirement for the prelink step. The advantage of using the binder is that the resulting executable program is fully rebindable. For information on how to use the binder, see z/OS DFSMS Program Management.

For information on how to build and use DLLs, see Chapter 4, “Building and Using Dynamic Link Libraries (DLLs),” on page 43.

Which Programs Need to Be Prelinked

The prelink step is required when an executable program is to reside in a PDS, or if it utilizes the system programming facilities of C. When the executable is to reside in a PDSE or HFS, the prelink step may be eliminated since the binder can handle the output of the C, C++, COBOL, and VisualAge PL/I compilers. If the link-edit process is performed by the linkage editor then the prelink step is required.

You should not use the pre-linker with XPLINK programs because XPLINK programs require the GOFF binder format and GOFF is not supported by the pre-linker. Also, the C/C++ compiler creates GOFF object code when the XPLINK compiler option is specified. When bound, the objects must reside in PDSEs or the HFS.

The following list identifies programs which may need to be prelinked before the link-edit step of creating an executable program.

- Modules which must be processed with the linkage editor rather than the binder
- Modules which must be stored in a PDS rather than in a PDSE
- Programs which utilize the system programming facilities of C.
- Non-XPLINK C programs compiled with any of the following compiler options:
  - RENT
  - LONGNAME
  - DLL
- Non-XPLINK C++ programs
- COBOL programs compiled with any of the following compiler options:
  - DLL
  - PGMNAME(LONGMIXED)
  - PGMNAME(LONGUPPER)
- COBOL programs that use object-oriented extensions
- COBOL programs containing class definitions or the INVOKE statement
- VisualAge PL/I programs
- Programs compiled to run under z/OS UNIX
Prelinking Applications

Only C object modules that do not refer to writable static, do not contain the LONGNAME option, and do not contain DLL code can be processed by the linkage editor. You do not need to prelink naturally reentrant programs. For more information, see “Making Your C/C++ Program Reentrant” on page 139.

If you need to link-edit together object modules and load modules, prelink the object modules through the prelinker in a single step, and then link-edit with the load modules in a separate link-edit step. This is because the prelinking process can only process object modules.

What the Prelinker Does

The prelinker performs the following functions:

- Collects information for run-time initialization, including data initialization for C/C++, constructor/destructor calls for static objects in C++, and DLL initialization information.
- For C object modules compiled with RENT, C++ programs, VisualAge PL/I programs, or COBOL programs with OO extensions, the prelinker:
  - Combines writable static initialization information
  - Assigns relative offsets to objects in writable static storage
  - Removes writable static name and relocation information
- For programs containing longnames, such as C programs compiled with LONGNAME, C++ programs, VisualAge PL/I programs, and COBOL programs compiled with PGMNAME(LONGMIXED) or PGMNAME(LONGUPPER), the prelinker maps LONGNAME option to SHORTNAME option on output.
- For programs that use DLLs, the prelinker:
  - Generates a function descriptor in writable static for each DLL referenced function
  - Generates a variable descriptor for each DLL referenced variable
  - Generates an IMPORT control statement for each exported function and variable
  - Generates internal information for the load module that describes symbols that are exported to and imported from other load modules
  - Combines static DLL initialization information
  - Uses longnames to resolve exported and imported symbols

Prelinking Process

Input to the prelinker includes the following:

- Primary input: those data sets and DLL definition side-decks that are allocated to SYSIN. If you are creating an application that imports symbols from DLLs, you must provide the definition side-deck for each DLL in SYSIN.
- Secondary input: input processed from SYSLIB, which contains object module libraries used for automatic library calls.
- Input specified in one or more INCLUDE control statements processed as primary and secondary input.

An attempt is made to read the DD or member of the DD (whichever is specified). This request is resolved if the read is successful.

If you are exporting symbols, the prelinker creates a definition side-deck. After the pre linker processes all its input, it puts the prelinked output object module into SYSMOD. If a definition side-deck was generated, it is put into SYSDEFSD and is a
sequential data set or a PDS member. The linking process then begins when the linkage editor takes its primary input from SYSLIN, which refers to the prelinked object module data set.

The IBM-supplied cataloged procedures and REXX EXECs for C/C++ use the DLL versions of the IBM-supplied class libraries by default; the IBM-supplied class libraries definition side-deck data set, SCLBSID, is included in the SYSIN concatenation.

If you are statically linking the relevant C/C++ class library object code, you must:
- Override the PLKED.SYSLIB concatenation to include the SCLBCPP data set, and
- Override the PLKED.SYSIN concatenation to exclude the SCLBSID data set.

Figure 176 shows an overview of the basic prelinking process.

---

**Figure 176. Basic Prelinker and Linkage Editor Processing**
Prelinking Applications

References to Currently Unresolved Symbols (Unresolved External References)

If, during the automatic library call, a symbol is not the name of an existing member of an object data set, the symbol can subsequently be defined if a function or variable with the same name is encountered. Unresolved requests generate error or warning messages to the prelinker map.

Writable static references that are not resolved by the prelinker cannot be resolved later. Only the prelinker can be used to resolve writable static. The output object module of the prelinker should not be used as input to another prelink.

If you are building an application that imports symbols from a DLL, you must include the definition side-deck produced by the prelinker when the DLL was built as input to the prelink step of your application.

If the symbol is an L-name that was not resolved by automatic library call and for which a RENAME statement with the SEARCH option exists, the symbol is resolved under the S-name on the RENAME statement by automatic library call. See "RENAME Control Statement" on page 578 for a complete description of the RENAME control statement.

Unresolved references or undefined writable static objects often result if the prelinker is given input object modules produced with a mixture of RENT/NORENT or LONGNAME/NOLONGNAME or DLL options. For more information on avoiding unresolved references in a DLL or in an application that imports symbols from a DLL, see z/OS C/C++ User’s Guide.

Processing the Prelinker Automatic Library Call

The following hierarchy is used to resolve a referenced and currently undefined symbol. In all cases, the symbol is only defined if it is contained in the input from this process or in other future input:

• The undefined name is an S-name, for example SNAME.
  If the NONCAL command option is in effect, the partitioned data sets concatenated to SYSLIB are searched in order as follows:
  – If the data set contains a C370LIB-directory created using the Object Library Utility, and the C370LIB-directory shows that a defined symbol by that name exists, the member of the PDS containing that symbol is read.
  – If the data set does not contain a C370LIB-directory created using the Object Library Utility and the reference is not to static external data, the member or alias, with the same name as SNAME, is read.

• The undefined name is an L-name.
  If the NONCAL command option is in effect, the partitioned data sets concatenated to SYSLIB are searched. If the data set contains a C370LIB-directory created using the Object Library Utility, and the C370LIB-directory shows that a defined symbol by that name exists, the member of the PDS indicated as containing that symbol is read.

Language Environment Prelinker Map

The Language Environment prelinker produces a listing file called the prelinker map when you use the MAP prelinker option (which is the default). As Figure 177 on page 574 shows, the prelinker map contains several individual sections that are only generated if they are applicable.
Figure 177. Prelinker Map (Part 1 of 2)
The numbers in the following text correspond to the numbers shown in the map.

1 **Heading**

   The heading is always generated and contains the product number, the library release number, the library version number, the date and the time the prelink step began, followed by a list of the prelinker options in effect for the step.

2 **Object Resolution Warnings**

   This section is generated if objects remained undefined at the end of the prelink step or if duplicate objects were detected during the step. The names of the applicable objects are listed.

3 **File Map**

   This section lists the object modules that were included in input. An object module consisting only of RENAME control statements, for example, is *not* shown. Also provided in this section are source origin (+ORIGIN), name (FILE NAME), and identifier (FILE ID) information. +ORIGIN indicates that the object module came from primary input because of:
   - An INCLUDE control statement in primary or secondary input.
   - A RENAME control statement.
   - The resolution of L-name library references.

---

*Figure 177. Prelinker Map (Part 2 of 2)*

The numbers in the following text correspond to the numbers shown in the map.
Prelinking Applications

- The object module was internal and self-generated by the prelink step.

The **FILE ID** can be found in other sections and is used as a cross-reference to the object module.

The **FILE NAME** can be either the data set name and, if applicable, the member name, or the ddbname and, if applicable, the member name.

If you are prelinking an application that imports variables or functions from a DLL, the variable descriptors and function descriptors are defined in a file called ***DESCRIPTORS***. This file has an origin of internal.

4 Writable Static Map

This section is generated if an object module was encountered that contains defined static external data. This area also contains variable descriptors for any imported variables and, if required, function descriptors. This section lists the names of such objects, their lengths, their relative offset within the writable static area, and a **FILE ID** for the file containing the object's definition.

Imported variables and DLL-referenced functions have angular brackets (<>) around their names in this section.

5 Load Module Map

This section is generated if the application imports symbols from other load modules. This section lists the names of the load modules.

6 Import Symbol Map

This section lists the symbols that are imported from other load modules. These otherwise unresolved DLL references are resolved through **IMPORT** control statements. It describes the type of symbol, that is, **D** (variable) or **C** (function). It also lists the file ID of the object module containing the corresponding **IMPORT** control statements, the module ID of the load module on that control statement, and the symbol name.

A DLL application would generate this section.

7 Export Symbol Map

This section lists the symbols generated by an object module that exports symbols. It describes the type of symbol, that is, **D** (variable) or **C** (function). It also lists the file ID of the object where the symbol is defined and the symbol name. Only externally defined data objects in writable static or externally defined functions can be exported.

Code that is compiled with the C, C++, or COBOL **EXPORTALL** compiler option or C/C++ code containing the **#pragma export** directive generates an object module that exports symbols.

**Note:** The export symbol map will NOT be produced if the NODYNAM option is in effect.

8 ESD Map of Defined and Longnames

This section lists the names of external symbols that are not in writable static. It also shows a mapping of input L-names to output S-names.

If the object is defined, the **FILE ID** indicates the file that contains the definition. Otherwise, this field is left blank. For any name, the input name and output S-name are listed. If the input name is an L-name, the rule used to map the L-name to the S-name is applied. If the name is not an L-name, this field is left blank.
Control Statement Processing

The only control statements processed by the prelinker are IMPORT, INCLUDE, LIBRARY, and RENAME. The remaining control statements are left unchanged until the link-edit step.

The control statements can be placed in the input stream or stored in a permanent data set.

Note: If you cannot fit all of the information on one control statement, you can use one or more continuations. The L-name, for example, can be split across more than one statement. Continuations are enabled by placing a nonblank character in column 72 of the statement that is to be continued. They must begin in column 16 of the next statement.

IMPORT Control Statement

The prelinker processes IMPORT statements, but does not pass them on to the link step. The IMPORT control statement has the following syntax:

Syntax

```
IMPORT CODE dll-name function
DATA dll-name variable
```

dll-name
The name or alias of the load module for the DLL. The maximum length of an alias is 8 characters. The dll-name can also be an HFS name; it must be enclosed in apostrophes if special characters, such as apostrophes or blanks, appear in the dll-name.

variable
An exported variable name; it is a mixed-case longname. Use a nonblank character in column 72 of the card to indicate a continuation and begin the next line in column 16.

function
An exported function name; it is a mixed-case longname. Use a nonblank character in column 72 of the card to indicate a continuation and begin the next line in column 16.

INCLUDE Control Statement

The INCLUDE control statement has the following syntax:

Syntax

```
INCLUDE filename
```
ddname
A ddname associated with a file to be included.

member
The member of the DD to be included.

The prelinker processes INCLUDE statements like the DFSMS linkage editor does with the following exceptions:
- INCLUDEs of identical member names are not allowed.
- INCLUDEs of both a ddname and a member from the same ddname are not allowed. The prelinker ignores the second INCLUDE.

**LIBRARY Control Statement**

The LIBRARY control statement has the following syntax:

```
LIBRARY name (member) (external)
```

name
The ddname defining a library. The ddname can point to an archive file in the HFS if the OE option is specified, or a PDS object library. The PDS object library can be a concatenation of one or more libraries created with or without the Object Library Utility.

member
The name or alias of a member of the specified library. Because both S-names and L-names can be specified, case distinction is significant.

Automatic library calls search the library and each subsequent library in the concatenation, if necessary, for the name instead of searching the primary input.

If you specify the OMVS or OE prelinker option, the only form of the LIBRARY card accepted by the prelinker is LIBRARY ddname, which specifies a library to search immediately for autocall.

external
An external reference that could be unresolved after primary input processing. This external reference will not be resolved by an automatic library call. Because both S-names and L-names can be specified, case distinction is significant.

The LIBRARY control statement is removed and not placed in the prelinker output object module; the system linkage editor does not see the LIBRARY control statement.

**RENAME Control Statement**

The RENAME control statement has the following syntax:
Syntax

\[
\text{RENAME } L\text{-name } S\text{-name } \text{SEARCH}
\]

**L-name**

The name of the input L-name to be renamed on output. All occurrences of this L-name are renamed.

**S-name**

The name of the output S-name to which the L-name will be changed. This name can be at most 8 characters and case is respected.

**SEARCH**

An optional parameter specifying that if the S-name is undefined, the prelinker searches by an automatic library call for the definition of the S-name. SEARCH is not supported under z/OS UNIX.

The RENAME control statement is processed by the prelinker and can be used for several purposes:

- To explicitly override the default name given to an L-name when an L-name is mapped to an S-name.

You can explicitly control the names presented to the system linkage editor so that external variable and function names are consistent from one linkage editor run to the next. This consistency makes it easier to recognize control section and label names that appear in system dumps and linkage editor listings. Another mapping rule (described in "Mapping L-Names to S-Names" on page 580) can provide the suitable name, but if you need to replace the linkage editor control section, you need to maintain consistent names.

- To explicitly bind an L-name to an S-name. This binding might be necessary when communicating with objects from other language and assembler processors, because these processors generate only S-names.

- A RENAME control statement cannot be used to rename a writable static object because its name is not contained in the output from the prelinker.

RENAME control statements can be placed before, between, or after other control statements or object modules. An object module can contain only RENAME statements. Also, RENAME statements can be placed in input that is included because of other RENAME statements.

**Usage Notes**

- A RENAME statement is ignored if the L-name is not encountered in the input.

- A RENAME statement for an L-name is valid provided all of the following are true:
  - The L-name was not already mapped because of a rule that preceded the RENAME statement rule in the hierarchy described in "Mapping L-Names to S-Names" on page 580.
  - The L-name was not already mapped because of a previous valid RENAME statement for the L-name.
  - The S-name is not itself an L-name. This rule holds true even if the S-name has its own RENAME statement.
Prelinking Applications

- A previous valid RENAME statement did not rename another L-name to the same S-name.
- Either the L-name or the S-name is not defined. Either the L-name or the S-name can be defined, but not both. This rule holds true even if the S-name has its own RENAME statement.

Mapping L-Names to S-Names

The output object module of the prelinker can be used as input to a system linkage editor.

Because system linkage editors accept only S-names, the Language Environment prelinker maps L-names to S-names on output. S-names are not changed. L-names can be up to 160 (COBOL for OS/390 & VM and COBOL for MVS & VM), 255 (z/OS C/C++), or 1024 (z/OS C++) characters in length; truncation of the L-names to the 8-character S-name limit is therefore not sufficient because collisions can occur.

The Language Environment prelinker maps a given L-name to an S-name according to the following hierarchy:

1. **C/C++ only**: If any occurrence of the L-name is a reserved run-time name, or was caused by a #pragma map or #pragma CSECT directive, then that same name is chosen for all occurrences of the name. This name must not be changed, even if a RENAME control statement for the name exists. For information on the RENAME control statement, see "RENAME Control Statement" on page 578.

2. If the L-name was found to have a corresponding S-name, the same name is chosen. For example, D0TOTALS is coded in both a C and assembler program. This name must not be changed, even if a RENAME statement for the name exists. This rule binds the L-name to its S-name.

3. If a valid RENAME statement for the L-name is present, the S-name specified on the RENAME statement is chosen.

4. If the name corresponds to a Language Environment function or library object for which you did not supply a replacement, the name chosen is the truncated, uppercased version of the L-name library name (with _ mapped to @). The S-name is not chosen, if either:
   - A valid RENAME statement renames another L-name to this S-name. For example, the RENAME statement RENAME mybigname PRINTF would make the library printf() function unavailable if mybigname is found in input.
   - Another L-name is found to have the same name as the S-name. For example, explicitly coding and referencing SPRINTF in the C source program would make the library sprintf() function unavailable.

Avoid such practices to ensure that the appropriate Language Environment function is chosen.

5. If the UPCASE option is specified, names that are 8 characters or fewer are changed to uppercase (with _ mapped to @). Names that begin with IBM or CEE will be changed to IB$, and CE$, respectively. Because of this rule, two different names can map to the same name. You should therefore use the UPCASE option carefully. A warning message is issued if a collision is found, but the names are still mapped.

6. If none of the above rules apply, a default mapping is performed. This mapping is the same as the one the compiler option NOLONGNAME uses for external names, taking collisions into account. That is, the name is truncated to 8 characters and changed to uppercase (with _ mapped to @). Names that begin
with IBM or CEE will be changed to IB$ and CE$, respectively. If this name is the same as the original name, it is always chosen. This name is also chosen if a name collision does not occur. A name collision occurs if either

- The S-name has already been seen in any input, that is, the name is not new.
- After applying this default mapping, the same name is generated for at least two, previously unmapped, names.

If a collision occurs, a unique name is generated for the output name. For example, the name @ST00033 is manufactured.

z/OS C/C++: A program that is compiled with the NOLONGNAME compiler option and link-edited, except for collisions, library renames, and user renames, presents the linkage editor with the same names as when the program is compiled with the LONGNAME option and processed by the prelinker.

Starting the Prelinker under Batch and TSO/E

The following sections describe how to start the prelinker under Batch and TSO/E. For more information about prelinking z/OS C++ applications under batch, see z/OS C/C++ User’s Guide.

Under Batch

The prelinker is invoked by the following cataloged procedures:

- CBCCL: C++ compile, prelink, and link
- CBCCLG: C++ compile, prelink, link, and run
- CBCL: C prelink and link
- CBCLG: C prelink, link, and run
- EDCPL: C prelink and link
- EDCPLG: C compile, prelink, link, and run.
- IGYWCPL: COBOL compile, prelink, link, and run
- IGYWPL: COBOL prelink and link
- IGYWCPG: COBOL compile, prelink, load, and run
- IBMZCPG: VisualAge PL/I compile, prelink, and load/run using the loader
- IBMZCPL: VisualAge PL/I compile, prelink, and link
- IBMZCPLG: VisualAge PL/I compile, prelink, and run

For more information about using these procedures, see z/OS C/C++ User’s Guide and VisualAge PL/I for OS/390 Programming Guide.

Under TSO/E

The Language Environment prelinker is started under TSO/E through an IBM-supplied CLIST called CPLINK, which invokes the prelinker and creates an executable module. If you want to create a reentrant C/C++ load module, link-edit C/C++ or COBOL object modules using long names, or create a DLL application, you must use CPLINK instead of the TSO/E LINK command.

The CPLINK command has the following syntax:
Prelinking Applications

**Syntax**

- **CPLINK**
  - **OBJ**(object)
  - **POPT**(options)
  - **PLIB**(libname)
  - **LOPT**(options)
  - **LIB**(libname)
  - **LOAD**(object)

**OBJ**

Specifies an input data set name. This is a required parameter. Each input data set must be one of the following:
- A C object module compiled with the RENT or LONGNAME compiler options
- A C object module that has no static external data
- A COBOL object module

**POPT**

Specifies a string of prelink options. The prelinker options available for CPLINK are the same as for batch. For example, if you want the MAP option to be used by the prelinker, specify the following:

CPLINK OBJ('dsname') POPT('MAP')...

When the prelink MAP option is specified (as opposed to the link option MAP), the prelinker produces a file showing the mapping of static external data. This map shows name, length, and address information. Any unresolved references or duplicate symbols during the prelink step are displayed in the map.
PLIB
Specifies the library names used by the prelinker for the automatic library call facility.

LOPT
Specifies a string of linkage editor options. For example, if you want the prelink utility to use the MAP option and the linkage editor to use the NOMAP option, use the following CLIST command:
CPLINK OBJ('dsname') POPT('MAP') LOPT('NOMAP...')

LIB
Specifies any additional library or libraries used by the TSO/E LINK command to resolve external references. These libraries are appended to the default language library functions.

LOAD
Specifies an output data set name. If you do not specify an output data set name, a name is generated for you. The name generated by the CLIST consists of your user prefix followed by CPOBJ.LOAD(TEMPNAME).

Examples
In the following example, your user prefix is RYAN, and the data set containing the input object module is a partitioned data set called RYAN.C.OBJ(INCCOMM). This example will generate a prelink listing without using the automatic call library. After the call, the load module is placed in a partitioned data set called RYAN.CPOBJ.LOAD(TEMPNAME) and the prelink listing is placed in a sequential data set called RYAN.CPOBJ.RMAP.
CPLINK OBJ('C.OBJ(INCCOMM)')

In the following examples, assume that your user prefix is DAVE, and the data set containing the input object module is a partitioned data set called DAVE.C.OBJ(INCPYRL). This example will not generate a prelink listing, and the automatic call facility will use the library HOOVER.LIB.SUB. The load module is placed in the partitioned data set DAVE.TBD.LOAD(MOD).

Figure 178. Example of Prelinking under Batch

```clist
CPLINK OBJ('''DAVE.C.OBJ(INCPYRL)''')
POPT('NOMAP,NONCAL')
PLIB('''HOOVER.LIB.SUB''')
LOAD('TBD.LOAD(MOD)')
```

Figure 179. Example of Prelinking under TSO/E
Prelinking Applications

Using the CXXBIND EXEC under TSO/E

For a description of using the CXXBIND EXEC to build a C++ executable program without using the prelink step, see z/OS C/C++ User’s Guide.

Using the CXXMOD EXEC under TSO/E

This section describes how to prelink and link your C++ or COBOL program by invoking the CXXMOD EXEC. This exec creates an executable module. The syntax for the CXXMOD EXEC is:

```
Syntax

CXXMOD OBJ (object)

POPT (prelink-option)

PLIB (libname)

LOPT (link-option)

LIB (libname)

PMOD (prelink-object)

LOAD (module)

PMAP (prelink-map)

LIST (listing)

PDEF (prelink-object)

OBJ
```

You must always specify the input data set names on the OBJ keyword parameter. Each input data set must be a C/C++, COBOL, or assembler object module.
If the high-level qualifier of an object data set is not the same as your user prefix, you must use the fully qualified name of the data set and place single quotation marks around the entire name.

**POPT**

Prelinker options can be specified using the POPT keyword parameter. If the MAP prelink option is specified, a prelink map will be written to the data set specified under the PMAP keyword parameter. For more details on generating a prelink map, see the description of the PMAP option.

**LOPT**

Linkage editor options can be specified using the LOPT keyword parameter. For details on how to generate a linkage editor listing, see the option LIST.

**PLIB**

The library names that are to be used by the automatic call library facility of the prelinker must be specified on the PLIB keyword parameter. The default library used is the C++ base library, CEE.SCEECPP.

The default library names are not added if library names are specified with the PLIB keyword parameter.

If the high-level qualifier of a library data set is not the same as your user prefix, you must use the fully qualified name of the data set and place single quotation marks around the entire name.

**LIB**

If you want to specify libraries for the link-edit step to resolve external references, use the LIB keyword parameter. The default library used is the Language Environment library, CEE.SCEELKED.

The default library names are not added if library names are specified with the LIB keyword parameter.

If the high-level qualifier of a library data set is not the same as your user prefix, you must use the fully qualified name of the data set and place single quotation marks around the entire name.

**PMOD**

If you want to keep the output prelinked object module, specify the data set it should be placed in using the PMOD keyword parameter. The default action is to create a temporary data set and erase it after the link-edit is complete.

If the high-level qualifier of the output prelinked object module is not the same as your user prefix, you must use the fully qualified name of the data set and place single quotation marks around the entire name.

**LOAD**

To specify where the resultant load module should be placed, use the LOAD keyword parameter.

If the high-level qualifier of the load module is not the same as your user prefix, you must use the fully qualified name of the data set and place single quotation marks around the entire name.

**LIST**

To specify where the linkage editor listing should be placed, use the LIST keyword parameter.

If the high-level qualifier of the linkage editor listing is not the same as your user prefix, you must use the fully qualified name of the data set and place single quotation marks around the entire name.

**PMAP**

To specify where the prelinker map should be placed, use the PMAP keyword parameter.

If the high-level qualifier of the prelinker map is not the same as your user prefix, you must use the fully qualified name of the data set and place single quotation marks around the entire name.
Prelinking Applications

PDEF To specify where the generated IMPORT control statements should be placed by the prelinker.

If the high-level qualifier of the prelinker map is not the same as your user prefix, you must use the fully qualified name of the data set and place single quotation marks around the entire name.

Prelinker Options

The following table describes the Language Environment prelinker options.

<table>
<thead>
<tr>

Prelinking Applications
Appendix B. EXEC DLI and CALL IMS Interfaces

There are two major approaches to accessing DL/I databases on IMS. This section describes the interfaces that are supported in the various environments, specifically IMS and CICS.

- **EXEC DLI approach**
- **CALL IMS approach**, which includes interfaces, such as: PLITDLI, CBLTDL1, and CTDLI.

Either an IMS library or a CICS library should be present when linking an application. If both libraries are available, link-edit errors may occur.

If you are using ILC in CICS DL/I applications, EXEC CICS DLI and CALL xxxTDLI can only be used in programs with the same language as the main program. For details on using ILC under CICS, see [z/OS Language Environment Writing Interlanguage Communication Applications](#).

Table 84 lists the IMS and CICS support for various user interfaces to DL/I databases.

Appendix C. Guidelines for Writing Callable Services

If you want to write services similar in form and description to Language Environment callable services, follow the guidelines listed below.

- Callable service parameters must follow the data type descriptions outlined in [z/OS Language Environment Programming Reference](https://www.ibm.com/support/manuals/zoslmrgl).
- Argument passing is by one level of indirection, either “by reference” or “by value”. See [ Passing Arguments between Routines](https://www.ibm.com/support/manuals/zoslmrgl) on page 132 for these argument passing styles.
- Avoid the use of operating system services and macros. Use Language Environment services whenever possible.
- Always use the prototype definition or the entry declaration whenever possible.
- Avoid using the CEE3SPM callable service (see [z/OS Language Environment Programming Reference](https://www.ibm.com/support/manuals/zoslmrgl)). CEE3SPM can change the condition handling semantics of the HLLs supported by Language Environment.
- Language Environment assumes the following defaults for character strings:
  - For input arguments, a length-prefixed string (with the length of the 2-byte prefix not included in the length value)
  - For output arguments, a fixed-length string of 80 bytes, padded on the right with blanks as necessary.
- Allow a feedback code area to be optionally passed as the last parameter to the callable service. The feedback code must be a FEED BACK data type and conform to the layout described in [Chapter 18, “Using Condition Tokens,”](https://www.ibm.com/support/manuals/zoslmrgl) on page 285.
- If omitted arguments are permitted by the HLL, a zero or NULL pointer must be used to indicate the omitted parameter in the parameter list that is passed to the callable service. For example:

<table>
<thead>
<tr>
<th>address of parm1</th>
</tr>
</thead>
<tbody>
<tr>
<td>address of parm2</td>
</tr>
<tr>
<td>0</td>
</tr>
</tbody>
</table>

The last parameter passed in the list must have the high-order bit on to indicate that it is last. If the last parameter is omitted, the zero value that the user passes in the parameter list must have the high-order bit on, for example X'80000000'. Therefore, you must allow the user of the callable service to check for this bit when the last parameter passed to the service is omitted.

- When documenting callable services, follow the same general format used to document each of the callable services in this book. Each callable service description should contain (in this order):
  - A general description of what the service does
  - A diagram indicating the syntax of the call to the service
  - A complete description of each callable service parameter and an identification of the required data type
  - A list of possible feedback codes that can be returned by the service to its caller
Writing Callable Services

- Usage notes that provide additional needed information to the user, such as a list of related callable services
- An example or examples of usage
Appendix D. Operating System and Subsystem Parameter List Formats

This appendix describes the various formats of parameters passed to and from operating systems and subsystems. In most cases you do not need to know these formats in order to pass or receive parameters in your application. For cases in which you want to directly access the parameter list that is passed, the format and contents of the parameter list are shown below.

There are additional considerations depending on whether the main routine is in the C, C++, COBOL, or PL/I language. For information about parameter passing in these languages, see:

- "C and C++ Parameter Passing Considerations"
- "COBOL Parameter Passing Considerations" on page 599
- "PL/I Main Procedure Parameter Passing Considerations" on page 601

C and C++ Parameter Passing Considerations

C and C++ generally support a single character string as a parameter to a main routine. They parse the string into tokens that are accessed by the argc and argv parameters of the main function.

In addition, there are alternate styles of passing a set of parameters to the main routine, for example: as a single value, a pointer to a value, or a pointer to a list of values. In these cases, the set of parameters is not parsed. It is assumed that the invoker of the application (for example, the operating system) has stored the address of the set of parameters in register 1 prior to entry into the main routine. Depending on how the parameters are passed, register 1 points on entry to the entities illustrated in Figure 180.

| Style 1: Register 1 contains parameter value |
| Register 1 = parameter value |

| Style 2: Register 1 contains pointer to parameter value |
| Register 1 = pointer \(\rightarrow\) parameter value |

| Style 3: Register 1 contains pointer to array of pointers to parameter values |
| Register 1 = pointer \(\rightarrow\) (pointer0 \(\rightarrow\) value0) (pointer1 \(\rightarrow\) value1) (pointer2 \(\rightarrow\) value2) ... (pointern \(\rightarrow\) valuen) |

Figure 180. Some Alternate C/C++ Parameter Passing Styles

The first arrangement in Figure 180 can be used only for parameters that are integers.
A C main routine elects to use one of the styles shown in Figure 180 on page 593 by specifying the PLIST(OS) run-time option in #pragma runopts (see "C PLIST and EXECOPS Interactions" on page 595); a C++ routine elects to use one of the styles with the PLIST(OS) compiler option (see "C++ PLIST and EXECOPS Interactions" on page 597). The main routine must know which parameter style to expect. When PLIST(OS) is specified, C or C++ makes the parameter list available through a pair of macros; code them in your main routine to determine which parameter list style your routine receives:

__R1 of type void *
--R1 contains the value that is in register 1 on entry into the main routine. It provides access to the parameters when they are passed according to the first two styles shown in Figure 180 on page 593.

__osplist of type void **
__osplist acts as an array of pointers to parameters. It is derived from __R1 and provides access to the parameters when they are passed according to the third style shown in Figure 180 on page 593. You must include the header file stdlib.h when using __osplist.

The third style is also supported for certain macros and functions (for example, __pcblst and __csclst for invokers IMS and Cross System Product). __osplist is a generalization of the more specialized __pcblst and __csclst macros; it can be used in their place or in cases where they do not apply.

Figure 181 illustrates how these macros can be used to access items in the three alternate parameter arrangements.

<table>
<thead>

</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>

Figure 181. Accessing Parameters Using Macros __R1 and __osplist

Suitable casting and dereferencing are required when using these macros, as shown in Figure 182 on page 595, according to the parameter passing style in use.

C PLIST and EXECOPS Interactions

You can use C `#pragma runopts` to specify to the C compiler a list of options to be used at run time. Two of the options of `#pragma runopts` affect the format of the argument list passed to the application on initialization: EXECOPS and PLIST.

EXECOPS allows you to specify run-time options on the command line or in JCL at application invocation. NOEXECOPS indicates that run-time options cannot be so specified. When the EXECOPS run-time option is specified under MVS, Language Environment alters the MVS parameter list format: Language Environment removes any run-time options that are present.

PLIST indicates in what form the invoked routine should expect the argument list. You can specify PLIST with the following values under Language Environment:

- **HOST** The argument list is assumed to be a character string. The string is located differently under various systems as follows:
  - Under TSO, if a CPPL is detected, Language Environment gets the string from the command buffer.
  - Under TSO, if a CPPL is not detected, Language Environment assumes a halfword-prefixed string in the MVS format.
  - Under MVS, Language Environment uses the halfword-prefixed string.

- **OS** The inbound parameter list is assumed to be in an MVS linkage format in which register 1 points to a parameter address list. No run-time options are available. Register 1 is not interrogated by Language Environment.

The PLIST(HOST) setting allows the object to execute under MVS (assuming a halfword-prefixed string), or under TSO (using the CPPL or the MVS-format parameter list). Specify PLIST(HOST) to default to the argument list format for the operating system under which your application is running.

Although Language Environment supports the MVS, IMS, and TSO suboptions of PLIST for compatibility, use of PLIST(HOST) is recommended. There are some exceptions to this guideline:

**Preinitialization**

PLIST(MVS) is supported for compatibility with pre-Language Environment C preinitialization programs.

---

*Figure 182. Examples of Casting and Dereferencing*
Operating System and Subsystem Parameter Lists

CICS If you are running a CICS application compiled under the pre-Language Environment-conforming version of C, PLIST(HOST), the default, is assumed regardless of the actual PLIST setting. If you are running a CICS application compiled with a Language Environment-conforming C compiler, specify PLIST(OS).

TSO TSO command processors that require access to the full CPPL must specify PLIST(OS).

The EXECOPS, NOEXECOPS, and PLIST options can alter the format of the argument list passed to your application, depending on the combination of options specified. The setting of EXECOPS determines whether Language Environment looks for run-time parameters in the inbound parameter list. The effects of the interactions of these options under the various operating systems and subsystems are summarized in Table 85.

C++ PLIST and EXECOPS Interactions

The EXECOPS compiler option allows you to specify run-time options on the command line or in JCL at application invocation. NOEXECOPS indicates that run-time options cannot be so specified. When the EXECOPS compiler option is specified under MVS, Language Environment alters the MVS parameter list format by removing any run-time options present.

The PLIST compiler option indicates in what form the invoked routine should expect the argument list. You can only specify PLIST with the following value under Language Environment:

**OS** The inbound parameter list is assumed to be in an MVS linkage format in which register 1 points to a parameter address list. No run-time options are available. Register 1 is not interrogated by Language Environment.

The EXECOPS, NOEXECOPS, and PLIST compiler options can alter the format of the argument list passed to your application, depending on the combination of options specified. The setting of EXECOPS determines whether Language Environment looks for run-time parameters in the inbound parameter list. The effects of the interactions of these options under MVS, TSO, and the various subsystems are summarized in Table 86 on page 598.

</tbody>
</table>
Case Sensitivity under TSO

When executing under TSO with the IBM-supplied default setting of PLIST(HOST), Language Environment dynamically determines whether a command processor parameter list (CPPL) has been passed. If so, an application with a C or C++ main routine receives the TSO parameter list in an argc, argv format.

If PLIST(TSO) is in effect, the inbound parameter list is a CPPL pointed to by R1. C treats PLIST(TSO) as PLIST(HOST). A user can access the CPPL using the __osplist macro if the user specifies PLIST(OS).

Arguments passed in TSO might be case-sensitive, depending on how your C or C++ program is invoked. Table 87 shows when the arguments are case-sensitive, based on how the C or C++ program is invoked.

<table>
<thead>
<tr>
<th>How C or C++ Program Is Invoked</th>

</tbody>
</table>

Parameter Passing Considerations with XPLINK C and C++

C and C++ code compiled with the XPLINK option builds parameter lists using the same logical format. However, the compiler may optimize some of the parameters into registers. See [z/OS Language Environment Vendor Interfaces](https://www.ibm.com) for more information.

COBOL Parameter Passing Considerations

COBOL users cannot explicitly set the PLIST and EXECOPS run-time options for an enclave containing a COBOL main program. When COBOL is the main program, Language Environment sets the argument list passed to the application on initialization as follows:

z/OS (non-CICS)

- If the COBOL main is invoked via the ATTACH SVC, a halfword-prefixed string is passed to the application after run-time options have been removed. The source of this string is dependent on the environment in which the ATTACH is issued, as follows:
  - If the ATTACH is issued by z/OS to invoke a batch program, the string is specified via the EXEC statement’s PARM field.
  - If the ATTACH is issued by TSO to attach a Command Processor (CP), the string is specified as part of the command embedded within the CP parameter of the TSO ATTACH CP command.
  - Otherwise, the string is specified via the PARM field of the ATTACH macro.
Operating System and Subsystem Parameter Lists

Note: The parameter list processing when COBOL is invoked with the ATTACH SVC can be altered with the COBOL parameter list exit IGZEPSX so that register 1 and the argument list are passed without change. If your program is not seeing the behavior mentioned above, then see your system programmer to determine what changes were made to the COBOL parameter list exit. For information on the COBOL parameter list exit, see \textit{z/OS Language Environment Customization}.

If changing IGZEPSX is not an approach that can be used in your environment, another approach is to ATTACH to a Language Environment-conforming assembler routine with MAIN=YES and PLIST=OS on the CEEENTRY macro. The Language Environment-conforming assembler routine can then invoke the COBOL program, passing the unchanged contents of register 1 (the address of the parameter list) to the COBOL program.

- If the COBOL main is not invoked by the ATTACH SVC, the halfword-prefixed string provided by the caller is passed to the application after run-time options have been removed if the following linkage is used:
  - The caller of the COBOL program provides an RSA that contains a back chain (HSA) field of binary 0.
  - Register 1 is nonzero.
  - The word addressed by Register 1 (the first parameter pointer word) has the End of List (EOL) bit on and the parameter it addresses is aligned on a halfword or greater boundary.

- Otherwise register 1 and the argument list are passed without change.

TSO

- In addition to the above z/OS (non-CICS) considerations, if the COBOL main is invoked from a REXX clist, parameter list processing depends on the method used to invoke the COBOL program.
  - If Address TSO (the default) or Address ATTCHMVS is used, the halfword-prefixed string provided by the caller is passed to the application after run-time options have been removed.
  - If Address LINKMVS is used, the halfword-prefixed string provided by the caller is passed unchanged to the application program.
  - Address LINK, Address ATTACH, Address LINKPGM, and Address ATTCHPGM are not supported since they use a different convention for parameter lists and save area chaining.

z/OS UNIX

- The parameter list consists of three parameters passed by reference:
  - Argument-count: a binary fullword integer containing the number of elements in each of the arrays that are passed as the second and third parameters.
  - Argument-length-list: an array of pointers. The Nth entry in the array is the address of a fullword binary integer containing the length of the Nth entry in the Argument-list (the third argument).
  - Argument-list: an array of pointers. The Nth entry in the array is the address of the Nth character string passed as an argument on the spawn(), exec(), or command invocation.

CICS

- If the COBOL main is invoked in a CICS environment, register 1 is passed without change.
PL/I Main Procedure Parameter Passing Considerations

The format of the parameter list passed to a PL/I main procedure from the operating system is controlled by the SYSTEM compiler option and also by options on the main PROCEDURE statement.

The SYSTEM compiler option specifies the format used to pass parameters to the PL/I main procedure, and indicates the host system under which the program runs: MVS, CICS, IMS, or TSO. The SYSTEM option allows a program compiled under one system to run under another.

The NOEXECOPS procedure option indicates that run-time options are not present in the operating system parameter list. The NOEXECOPS option can be explicitly specified or implicitly defaulted. Otherwise, it is assumed that run-time options might be present in the operating system parameter list. If present, these run-time options are removed by run-time initialization before the PL/I main procedure gains control.

In order for run-time options to be passed in the operating system parameter list for SYSTEM(MVS), the PL/I main procedure must receive no parameters or receive a single parameter that is a varying character string. If this is not the case, NOEXECOPS is always defaulted.

The OPTIONS(BYVALUE) or OPTIONS(BYADDR) procedure options indicate if the main procedure parameters are passed directly or indirectly. If SYSTEM(IMS) or SYSTEM(CICS) is specified for a VisualAge PL/I or a PL/I for MVS & VM main procedure, the OPTIONS(BYVALUE) procedure option is defaulted at compilation time, OPTIONS(BYADDR) is not permitted. When SYSTEM(CICS) and SYSTEM(IMS) is specified, Language Environment remaps the parameters to match the OPTIONS attribute BYADDR or BYVALUE of the main procedure. See “Passing Arguments between Routines” on page 132 for additional information about Language Environment parameter passing.

The following tables describe the interaction of the PL/I SYSTEM and NOEXECOPS options. Their effect is described in terms of the parameters that are coded on the MAIN procedure statement and also the incoming system, subsystem, or assembler parameter list as initially received by Language Environment.

<table>
<thead>
<tr>
<th>SYSTEM Setting</th>
<th>No Run-Time Options (NOEXECOPS)</th>
<th>Run-Time Options Can Be Present</th>
</tr>
</thead>
<tbody>
<tr>
<td>SYSTEM(MVS)</td>
<td>If the main procedure parameter is a single varying character string, an MVS parameter list is assumed and repackaged so the main procedure receives a halfword-prefixed string. The entire string is passed to the main procedure without change. Otherwise, the parameter list is passed without change.</td>
<td>If the main procedure parameter is a single varying character string, an MVS parameter list is assumed and repackaged so the main procedure receives a halfword-prefixed string. ### Table 88. Interactions of SYSTEM and NOEXECOPS (continued)

<table>
<thead>
<tr>
<th>SYSTEM Setting</th>
<th>No Run-Time Options (NOEXECOPS)</th>
<th>Run-Time Options Can Be Present</th>
</tr>
</thead>
</table>

#### Notes:

1. NOEXECOPS is always implied for SYSTEM(CICS), SYSTEM(IMS), and SYSTEM(TSO). NOEXECOPS is also implied for SYSTEM(MVS), if the main procedure has more than one parameter or a single parameter that is not a varying character string.

2. In an IMS environment, if an assembler program is driving a PL/I transaction where LANG is not specified or LANG=NON-PLI (except Pascal) under IMS V4R1, the parameter passes through without change. Otherwise, one level of indirection is removed from the parameter.

   If an assembler program is driving a transaction program written in VisualAge PL/I or PL/I for MVS & VM, the main procedure of the transaction must be compiled with SYSTEM(MVS) option; the main procedure receives the parameter list passed from the assembler program in MVS style.
Appendix E. Object Library Utility

The Object Library Utility is used to update libraries of object modules. A library is a partitioned data set (PDS or PDSE) with object modules as members.

Object libraries provide for convenient packaging of object modules. With the Object Library Utility, a library can contain object modules with L-names, object modules with S-names, and object modules with writable static data. The Object Library Utility is used to create information, such as which members contain defined L-names, S-names, or writable static data. This information is stored in a special member of the library that will be referred to as the Object Library Utility directory.

Commands to add object modules to a library, to delete object modules from a library, or to build the Object Library Utility directory for a library are available. Use the DIR command to build the Object Library Utility directory for a library of object modules. Use the MAP command to list the contents of the Object Library Utility directory.

Creating an Object Library

You can create an object library under batch or TSO.

Under Batch

Under MVS batch, the following cataloged procedures include an Object Library Utility step:

- **EDCLIB**  Maintain an object library.
- **EDCCLIB**  Compile and maintain an object library.

For more information about the data sets used with the Object Library Utility, see [z/OS C/C++ User's Guide](https://www.ibm.com/support/knowledgecenter/SSEPGG_1.2.0/com.ibm.zos.zos/contents/zos_c_c_user_guide.html).

You can specify options for the Object Library Utility step that generate a library directory, add or delete members of a directory, or generate a map of library members and defined external symbols. This section shows you how to specify these options under MVS batch.

To compile the C program WALTER.SOURCE(SUB1) for L-names and add to WALTER.SOURCE.OBJ(SUB1), use the following JCL. The Object Library Utility directory for the library, WALTER.SOURCE.OBJ, is updated in the process.

```jcl
//COMPILE EXEC EDCCLIB,INFILE='WALTER.SOURCE(SUB1)',CPARM='LO',
// LIBRARY='WALTER.SOURCE.OBJ',MEMBER='SUB1'
```

To request a map for the library WALTER.SOURCE.OBJ, use:

```jcl
//OBJLIB EXEC EDCLIB,OPARM='MAP',LIBRARY='WALTER.SOURCE.OBJ'
```

The following example creates a new Object Library Utility directory. If the directory already exists, it is updated:

```jcl
//DIRDIR EXEC EDCLIB,
// LIBRARY='LUCKY13.CXX.OBJMATH',
// OPARM='DIR'
```

To create a map:
Object Library Utility

To add new members to an object library, use the ADD option to update the directory. For example, to add a new member named MA191, code:

```
//ADDDIR  EXEC EDCLIB,
// LIBRARY='LUCKY13.CXX.OBJMATH',
// OPARM='ADD MA191',
// OBJECT='DSNAME=LUCKY13.CXX.OBJ(OBJ191),DISP=SHR'
```

To delete a member from an object library, use the DEL option to keep the directory up-to-date. For example, to delete a member named OLDMEM, code:

```
//DELDIR  EXEC EDCLIB,
// LIBRARY='LUCKY13.CXX.OBJMATH',
// OPARM='DEL OLDMEM'
```

Under TSO

The Object Library Utility has the following syntax:

```
   Syntax
  +----------------------------------+
     |                                 |
     | C370LIB                          |
     |                                  |
     | ADD LIB (libname(-membername-))  |
     |                                  |
     | DEL LIB (libname(-membername-))  |
     |                                  |
     | MAP LIB (libname-)               |
     |                                  |
     | DIR LIB (libname-)               |
     | LIST (-map-)                     |
  +----------------------------------+
```

ADD
Add (or replaces) an object module in an object library.

If the ADD function is used to insert an object module in a member of a library that already exists, the previous member is deleted prior to the insert unless the source data set is the same as the target data set, in which case the member is not deleted and only the Object Library Utility directory is updated as appropriate.

DEL
Deletes an object module from an object library.

MAP
Lists the names (entry points) of object library members.

DIR
Builds the Object Library Utility directory member. The Object Library Utility directory contains the names (entry points) of library members.

The DIR function is only necessary if object modules were previously added or deleted from the library without using C370LIB.

LIB (libname(membername))
Specifies the target data set for the ADD and DEL functions. The data set name must contain a member specification to indicate which member is to be created, replaced, or deleted.
OBJ *(objname)*

Specifies the source data set containing the object module that is to be added to the library. If you do not specify a data set name, the target data set specified in LIB(libname(membername)) is used as the source.

LIB *(libname)*

Specifies the object library for which a map is to be produced or for which an Object Library Utility directory is to be built.

LIST *(map)*

Specifies the data set that is to contain the library map. If an asterisk (*) is specified, the library map is directed to your terminal. If you do not specify a data set name, a name is automatically generated using the library name and the qualifier MAP. If the input library data set is called TEST.OBJ and your user prefix is FRANK, the data set name generated for the map is FRANK.TEST.OBJ.MAP.

Under TSO, you can use either the C370LIB CLIST or the CC CLIST using the parameter C370LIB. The C370LIB parameter of CC CLIST specifies that if the object module from the compile is directed to a member of a PDS, then the Object Library Utility directory is to be updated. This step is the equivalent to a compile and C370LIB ADD step. If the C370LIB parameter is specified and the object module is not directed to a member of a PDS, the C370LIB parameter is ignored.

Object Library Utility Map

The Object Library Utility produces a listing for a given library when the MAP command is specified. The listing contains information on each member of the library. A representative example is shown in [Figure 183 on page 606](#)
### Object Library Utility Map

Figure 183. Object Library Utility Map

1 Map Heading

The heading contains the product number, the compiler release number, the compiler version number, and the date and time the Object Library Utility step commenced. The name of the library immediately follows the heading. To the right of the name of the library is the start time of the last Object Library Utility step that updated the Object Library Utility directory.

2 Member Heading

The name of the object module member is immediately followed by the ID of the processor that produced the object module. The processor ID is based on the presence of an END record in the object module having the processor information in the appropriate format. If this information is not present, the Processor ID field is not listed.

The Timestamp field is presented in *yy/mm/dd* format. The meaning of the timestamp is enclosed in parentheses. That is, the Object Library Utility retains a timestamp for each member and selects the time according to the following hierarchy:
(P) Indicates that the timestamp is extracted from the object module from the date form of #pragma comment or from the timestamp form of #pragma comment, whichever comes first.

(D) Indicates that the timestamp is based on the time that the Object Library Utility DIR command was last issued.

(T) Indicates that the timestamp is the time that the ADD command was issued for the member.

3 User Comments
The user form of comments generated by #pragma comment is displayed. These comments are extracted from the END record. It is possible to manually add such comments on multiple END records and have them displayed in the listing. See z/OS C/C++ Language Reference for more information on the END record.

4 Symbol Information
Immediately following the Member Heading (and user comments, if any) is a list of the defined objects contained within that member. Each symbol is prefixed by Type information enclosed in parentheses and either External Name or Function Name. Function Name appears provided the object module was compiled with the LONGNAME option and the symbol is the name of a defined external function. In all other cases External Name is displayed. The Type field gives additional information on each symbol. That is:

'L' Indicates that the name is an L-name.

'S' Indicates that the name is an S-name.

'W' Indicates that this is a writable static object. If no 'W' is present, then this is not a writable static object.

'WL' Indicates that this is both an L-name and in writable static.
Object Library Utility

Appendix F. Using the Systems Programming Environment

Note: This section applies to C applications only.

As a C routine executes, facilities from the Language Environment common library are invoked to set up the execution environment in order to handle termination activities and provide storage management, error handling, run-time options parsing, ILC, and debugging support. In addition, the C library functions are in the Language Environment common library.

For situations in which not all of these services are needed, the system programming facilities of C can provide a limited environment.

System programming facilities allow you to run applications without using the Language Environment common library, or with just the C library functions, and to:

- Develop C applications that do not require the Language Environment common library on the machines on which they run.
- Use C as an assembler language substitute to, for example, write exit routines for MVS, TSO, or JES.
- Develop applications featuring:
  - A persistent C environment, in which a C environment is created once and used repeatedly for C function execution from any language.
  - Co-routines that use a two-stack model, as in client-server style applications. In this style, the user application calls on the applications server to perform services independently of the user and then return to the user.

For more information on the system programming facilities of C, see z/OS C/C++ Programming Guide.

This chapter discusses how to build these applications once you have compiled them with the C compiler. Note that you must compile these programs with the NOSTART option.

Building Freestanding Applications

Freestanding applications need to be linked with specific alternate initialization routines.

To explicitly include an alternative initialization routine under MVS, use the linkage editor INCLUDE and ENTRY control statements. To include the alternate initialization routines described in this chapter, you must allocate CEE.SCEESPC to the SYSLIB DD. For example, the following linkage editor control stream might be used to specify EDCXSTRT as an alternate initialization routine (another example is shown in Figure 186 on page 610):

```c
INCLUDE SYSLIB(EDCXSTRT)
ENTRY EDCXSTRT
INCLUDE SYSIN
```

Figure 184. Specifying Alternate Initialization at Link-Edit Time
When building freestanding applications under MVS, CEE.SCEESPC must be included in the link-edit SYSLIB concatenation. Also, if C library functions are needed, CEE.SCEESPC must precede CEE.SCEELKED.

The routines to support this function (EDCXSTRT and EDCXSTRL) are CEESTART replacements in your module. You must specify NOSTART compiler option when compiling the file that contains the main function. Therefore, the appropriate EDCXSTR$n$ routine must be explicitly included at link-edit.

A simple freestanding routine that requires a C library function is shown in Figure 185.

```c
#include <stdio.h>
main() {
    puts("Hello, World");
    return 3999;
}
```

*Figure 185. Simple Freestanding Routine*

This routine, RET3999, is compiled with nostart compiler option and link-edited using control statements shown in Figure 186. It is assumed that:

- The object module is available to the linkage-editor using an OBJECT DD statement.
- CEE.SCEESPC and CEE.SCEELKED libraries are specified on a SYSLIB DD statement.
- The intended load module member name is specified on a SYSLMOD DD statement.

The CEE.SCEERUN run-time load library must be available at run-time because it contains the C library function puts().

```c
INCLUDE SYSLIB(EDCXSTRL)
INCLUDE OBJECT
ENTRY EDCXSTRL
```

*Figure 186. Link-Edit Control Statements Used to Build a Freestanding MVS Routine*

Figure 187 on page 611 shows how to compile and link a freestanding program using the cataloged procedure EDCCL. See z/OS C/C++ Programming Guide for more information about EDCCL.
Special Considerations for Reentrant Modules

A simple freestanding routine that does not require C library functions is shown in Figure 188. This routine uses the `exit()` function, which is normally part of the C library but (like `sprintf()`) is available to freestanding routines without requiring the dynamic library. This routine is not naturally reentrant, but the resulting load module is reentrant.

```c
#include <stdlib.h>

int main() {
    static int i[5]={0,1,2,3,4};
    exit(320+i[1]);
}
```

The JCL required to build and execute this routine is shown in Figure 189 on page 612. The bracketed numbers in the figure refer to the comments that follow.
Notes

[189-1] The prelinker must be used for modules compiled with the RENT compiler option.

[189-2] This is the object module created by compiling the sample module with the RENT and NOSTART compiler options.

[189-3] The output from the prelinker is made available to the linkage editor.

[189-4] The alternate initialization routine (EDCXSTRT in this example) must be explicitly included in the module. If this is not the first CSECT in the module it must be explicitly named as the module entry point.

[189-5] The prelinked output is included in the load module.

[189-6] EDCXEXIT must be explicitly included if the exit() function is used in the application.

[189-7] The routine EDCRCINT must be explicitly included in the module if the RENT compiler option is used. No error is detected at load time if this routine is not explicitly included. At execution time, abend 2106, reason code 7205, results if EDCRCINT is required but not included.

Figure 189. Building and Running a Reentrant Freestanding MVS Routine
Building System Exit Routines

There are no special considerations for building system exit routines. These routines can be linked with their callers or dynamically loaded and invoked. CEE.SCEESPC must be available at link-edit. If C library functions are required by the exit routines, the CEE.SCEELKED library must also be made available after CEE.SCEESPC. If the routines were compiled with OPT(2), the entry point must be explicitly named in the link-edit input.

Note: You must compile these programs with the NOSTART option.

Building Persistent C Environments

There are no special considerations for building applications that use persistent C environments. The data set CEE.SCEESPC contains the object modules to be included.

If C library functions are required by any routine called in this environment, the library stub routines should also be made available at link time after CEE.SCEESPC.

Note: You must compile these programs with the NOSTART option.

Building User-Server Environments

To build your server application, follow the rules for building a freestanding application as described in “Building Freestanding Applications” on page 609.

There are no special considerations for building user applications. The automatic call facility causes the right routines from SYSLIB to be included.

Note: You must compile servers with the NOSTART option.

Systems Programming Environment
Appendix G. Sort and Merge Considerations

This chapter discusses the run-time aspects of sort and merge operations. For details on the compile-time aspects of sort and merge, including instructions on coding the sort and merge procedures, see your compiler programming guide.

Understanding the Basics

Under Language Environment, you can invoke the sort facility to sort or merge records in a particular sequence. A sort operation takes an unordered sequence of input data, arranges it according to a specified key or pattern, and places it into an output file. A merge operation compares two or more files that have already been sorted according to an identical key and combines them in a specified order in an output file.

To invoke the sort facility in Language Environment, you can use either of the following:

- An HLL construct
  - COBOL's SORT and MERGE statements. (The SORT and MERGE statements are not supported when running under z/OS UNIX.)
  - PL/I's PLISRTx interface, where x is replaced by A, B, C, or D
    You cannot call the PLISRTx interface under CICS.
- A method other than an HLL construct (for example, assembler routines, JCL, or ISPF).

Under Language Environment, your IBM sort/merge licensed program must be DFSORT™ or an equivalent that honors the DFSORT extended parameter list. Whenever DFSORT is mentioned in this chapter, you can use any equivalent SORT product.

Restriction: SORT and MERGE is not supported in a POSIX(ON) environment.

Invoking DFSORT Directly

For information about using the methods to run DFSORT directly with JCL or to invoke DFSORT directly from an assembler program, see [z/OS DFSORT Application Programming Guide](https://www.ibm.com/support/docview.wss?uid=swg27033105). Also see that book for details on DFSORT's many built-in features that you can use to eliminate the need for writing program logic (for example, the INCLUDE, OMIT, OUTREC, and SUM statements).

Using the COBOL SORT and MERGE Verbs

This section contains a high-level overview of COBOL SORT and MERGE verbs. It is designed to introduce you to concepts that help you understand some of the special considerations for using these COBOL statements in Language Environment. For a detailed description of how to use SORT and MERGE, see [Enterprise COBOL for z/OS Programming Guide](https://www.ibm.com/support/docview.wss?uid=swg27033105) or [COBOL for OS/390 & VM Programming Guide](https://www.ibm.com/support/docview.wss?uid=swg27033105).

A COBOL program that contains a sort operation can be organized so that an input procedure reads and operates on one or more input files before the files are actually sorted. To specify the input procedure:

SORT...INPUT PROCEDURE
Sort and Merge Considerations

You can also specify an output procedure that processes the files after they are sorted:
SORT...OUTPUT PROCEDURE

These input and output procedures can be used to add, delete, alter, edit, or otherwise modify the records.

You can also sort records under COBOL without any processing by the input and output procedures. For example, to read records into a new file for sorting without any preliminary processing, specify:
SORT...USING

To transfer sorted records to a file without any further processing, specify:
SORT...GIVING

User Exit Considerations

SORT or MERGE COBOL verbs can trigger COBOL-generated user exits (E15 for sort, E35 for merge). These exits include any input or output procedures. However, the exits are not triggered when a COBOL USING or GIVING statement is in effect and the files qualify for FASTSRT.

Language Environment treats the COBOL-generated exits differently than those requested by a direct invocation of DFSORT. Language Environment treats user exits triggered by COBOL SORT or MERGE as part of the enclave of the routine that invoked DFSORT; the SVC LINK used to invoke DFSORT is not considered by Language Environment to initiate a new implicit nested enclave. This is not the case for direct invocations of DFSORT, which do result in the creation of a new nested enclave. See Chapter 31, “Using nested enclaves,” on page 555 for more information on nested enclaves, and see z/OS DFSORT Application Programming Guide for more information on direct invocations of DFSORT.

Condition Handling Considerations

This section summarizes how Language Environment condition handling behaves when a Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM, COBOL/370, or VS COBOL II routine is involved in a SORT or MERGE.

Program Interrupts

User handlers established by the routine that initiated the SORT/MERGE are able to handle program interrupts as they are presented to the condition manager by a condition token. Normal condition handling as described in Chapter 15, “Language Environment Condition Handling Introduction,” on page 193 occurs.

Establishment of HLL-specific handlers and user handlers is not supported while in a SORT input or output procedure. The results are unpredictable, and the condition handler does not attempt to diagnose this case.

HLL-specific handlers and user handlers established by a routine called by an input or output procedure are able to handle program interrupts. However, because these exits are typically invoked many times (equivalent to the number of records being sorted for each exit), it is recommended that you register the handler within the application that initiated the SORT/MERGE in order to avoid overhead.
Language Environment-Signaled Conditions

HLL-specific handlers and user handlers established by the routine that initiated the SORT/MERGE are able to handle any condition signaled by Language Environment. Normal condition handling as described in Chapter 15, “Language Environment Condition Handling Introduction,” on page 193 occurs.

Abends

When there is an abend, the DFSORT ESTAE exit intercepts the abend, and performs various cleanups and recoveries. Informational dumps and messages are produced as appropriate. The abend is then percolated and eventually intercepted by the Language Environment ESTAE exit. Condition handling then continues as described in Chapter 15, “Language Environment Condition Handling Introduction,” on page 193.

By the time the Language Environment ESTAE exit intercepts the abend, the SORT has been terminated. Language Environment moves the current resume cursor to the return point where SORT was invoked and reflects the deletion of stack frames (and associated load modules) following the SORT invocation. Any user condition handlers associated with these stack frames (those following the SORT invocation) do not get control.

Using the PL/I PLISRTx Interface

This section contains a high-level overview of the PLISRTx interfaces to DFSORT. It is designed to introduce you to concepts that help you understand some of the special considerations for using these PL/I interfaces in Language Environment. For a detailed description of how to use PLISRTx, see VisualAge PL/I for OS/390 Programming Guide or PL/I for MVS & VM Programming Guide.

PL/I provides a SORT interface called PLISRTx. When you make a call to PLISRTx, you replace x with A, B, C, or D, depending on whether your input comes from a data set or a PL/I subroutine, and whether your output is to be written to a data set or processed by a PL/I subroutine:

- **PLISRTA**: Unsorted input is read from a data set and then sorted. The sorted output is written to a data set.
- **PLISRTB**: Unsorted input is provided and processed by a PL/I subroutine before sorting. The sorted output is written to a data set.
- **PLISRTC**: Unsorted input is read from a data set and then sorted. The sorted output is then processed by a PL/I subroutine.
- **PLISRTD**: Unsorted input is provided and processed by a PL/I subroutine before sorting. The sorted output is then processed by a PL/I subroutine.

In the call to PLISRTx, you also pass information about your data, using the SORT and RECORD arguments, and specify the maximum amount of storage you will allow DFSORT to use.

User Exit Considerations

Your input handling subroutine and output handling subroutine must be written in PL/I. PL/I generates a DFSORT E15 exit for your input handling subroutine and a DFSORT E35 exit for your output handling subroutine.
Sort and Merge Considerations

A call to one of the PLISRTx interfaces might trigger a call to user exit E15, E35, or both, depending on whether a subroutine is to process your input before sorting, or your output after sorting, as shown in Table 90.

Table 90. DFSORT Exit Called as a Function of a PLISRTx Interface Call

<table>
<thead>
<tr>
<th>PL/I Sort Interface</th>
<th>DFSORT Exit</th>
</tr>
</thead>
<tbody>
<tr>
<td>PLISRTA</td>
<td>None</td>
</tr>
<tr>
<td>PLISRTB</td>
<td>E15</td>
</tr>
<tr>
<td>PLISRTC</td>
<td>E35</td>
</tr>
<tr>
<td>PLISRTD</td>
<td>E15 and E35</td>
</tr>
</tbody>
</table>

Language Environment treats the generated E15 and E35 exits differently than those requested by a direct invocation of DFSORT. Language Environment treats user exits triggered by PLISRTx as part of the enclave of the routine that invoked DFSORT; the SVC LINK used to invoke DFSORT is not considered by Language Environment to initiate a new implicit nested enclave. See Chapter 31, “Using nested enclaves,” on page 555 for more information on nested enclaves, and see z/OS DFSORT Application Programming Guide for more information on direct invocations of DFSORT.

Condition Handling Considerations

Input and output handling subroutines can issue GOTOs. If you need to deactivate the SORT program for any reason while in one of these exits, issue a GOTO out of the subroutine.

Program Interrupts and Language Environment-Signaled Conditions

PL/I ON-units can be established in any of the following:
- The routine that made a call to PLISRTx
- The input(E15) or output(E35) procedure
- A routine called by the input or output procedure

These ON-units can handle program interrupts and Language Environment-signaled conditions. Normal condition handling, as described in Chapter 15, “Language Environment Condition Handling Introduction,” on page 193, occurs.

Abends

ON-units do not have the opportunity to handle abends that arise during a sort operation.

When there is an abend, the DFSORT ESTAE exit intercepts the abend and performs various clean-ups and recoveries. Informational dumps and messages are produced as appropriate. The abend is then percolated and eventually the Language Environment ESTAE exit intercepts it. Condition handling then continues as described in Chapter 15, “Language Environment Condition Handling Introduction,” on page 193.

By the time the Language Environment ESTAE exit intercepts the abend, the SORT has been terminated. Language Environment moves the current resume cursor to the return point where SORT was invoked and reflects the deletion of stack frames (and associated load modules) after the SORT invocation. Any user condition handlers associated with these stack frames (those following the SORT invocation) do not get control.
When running DFSORT (or an OEM SORT function), it is recommended that the TRAP(ON), or TRAP(ON,SPIE) Language Environment run-time option be specified. This will ensure that the Language Environment ESPIE is available to process expected internal Language Environment program interrupts.
Appendix H. Running COBOL Programs under ISPF

This appendix applies to COBOL users only.

When you code your application using ISPF panels, you can gain interactive access to your COBOL application.

Notes:
1. If you attempt to pass run-time options to a COBOL program that is invoked from ISPF, the run-time options will be treated as program arguments.
2. Enterprise COBOL for z/OS and OS/390, COBOL for OS/390 & VM, COBOL for MVS & VM and COBOL/370 programs are allowed to run concurrently in both screens of the ISPF split screen mode.

For detailed information about using ISPF, see the ISPF publications listed in "Bibliography" on page 635.
Appendix I. Language Environment Macros

The macros identified in this appendix are provided as programming interfaces for customers by Language Environment.

Attention:

Do not use as programming interfaces any Language Environment macros other than those identified in this appendix.

All macros listed here are provided as General-Use Programming Interfaces.

- CEECAA (see “CEECAA Macro — Generate a CAA Mapping” on page 488)
- CEEDESA (see “CEEDSA Macro — Generate a DSA Mapping” on page 489)
- CEEENTRY (see “CEEENTRY Macro — Generate a Language Environment-Conforming Prolog” on page 484)
- CEEFETCH (see “CEEFETCH Macro — Dynamically Load a Language Environment-Conforming Routine” on page 494)
- CEELOAD (see “CEELOAD Macro — Dynamically Load a Language Environment-Conforming Routine” on page 491)
- CEEPAA (see “CEEPAA Macro — Generate a PPA” on page 489)
- CEERELES (see “CEERELES Macro — Dynamically Delete a Language Environment-Conforming Routine” on page 498)
- CEETERM (see “CEETERM Macro — Terminate a Language Environment-Conforming Routine” on page 487)
- CEEOPT (see Chapter 9, “Using Run-Time Options,” on page 117)
- CEEPIT (see “Macros that generate the PreInit table” on page 517)
- CEEPITY (see “Macros that generate the PreInit table” on page 517)
- __csplist (see “C and C++ Parameter Passing Considerations” on page 593)
- __osplist (see “C and C++ Parameter Passing Considerations” on page 593)
- __pcblist (see “C and C++ Parameter Passing Considerations” on page 593)
- __R1 (see “C and C++ Parameter Passing Considerations” on page 593)
Language Environment Macros
Appendix J. PL/I Macros Which Activate Variables

Several PL/I macros shipped with Language Environment activate (%ACT) variables on behalf of the user program. They allow code developers to use common Language Environment data types. Use of these variable names by a user program will result in a compile error. Table 91 lists the macros and the preprocessor variable names.

These PL/I preprocessor variables correspond with the Language Environment data types of the same name. They should be used much as you would standard PL/I attributes. They may be used in combination with:

- storage class attributes (such as BASED)
- scope attributes (such as EXTERNAL)
- alignment attributes (such as ALIGNED)
- aggregation attributes, including dimensions and structure level numbers; in fact, some of the data types require the use of level numbers

The Language Environment data types must not be used in combination with:

- arithmetic attributes, including BASE, SCALR, MODE, PRECISION and PICTURE
- string attributes, including BIT, CHAR, GRAPHIC, VARYING and PICTURE
- program control data Attributes, including AREA, ENTRY, FILE, LABEL, OFFSET, POINTER, TASK and VARIABLE
- the LIKE attribute, although you can LIKEen another identifier to one declared using the Language Environment data types

It is strongly recommended that you always code the Language Environment data type as the last attribute in any identifier’s declaration. Unlike true PL/I attributes, order sometimes counts.

There is another difference between these Language Environment data types and true PL/I attributes: some of them may not be used as parameter descriptors (in the parameter list of the ENTRY attribute). Consequently, some of the data types are available in two forms: with and without a "_PARM" suffix. In these cases, you MUST use the _PARM version when you specify a parameter descriptor, and the other version in all other contexts.

One final difference between the Language Environment data types listed below and true PL/I attributes which you must be aware of is that the Language Environment data types must be treated as reserved words. Whereas PL/I attribute names may also be used as identifier names, the Language Environment data type names may not be used in any context other than that of an attribute.

Appendix K. Accessibility

Accessibility features help a user who has a physical disability, such as restricted mobility or limited vision, to use software products successfully. The major accessibility features in z/OS enable users to:

- Use assistive technologies such as screen readers and screen magnifier software
- Operate specific or equivalent features using only the keyboard
- Customize display attributes such as color, contrast, and font size

Using assistive technologies

Assistive technology products, such as screen readers, function with the user interfaces found in z/OS. Consult the assistive technology documentation for specific information when using such products to access z/OS interfaces.

Keyboard navigation of the user interface

Users can access z/OS user interfaces using TSO/E or ISPF. Refer to z/OS TSO/E Primer, z/OS TSO/E User's Guide, and z/OS ISPF User's Guide Volume I for information about accessing TSO/E and ISPF interfaces. These guides describe how to use TSO/E and ISPF, including the use of keyboard shortcuts or function keys (PF keys). Each guide includes the default settings for the PF keys and explains how to modify their functions.

z/OS information

z/OS information is accessible using screen readers with the BookServer/Library Server versions of z/OS books in the Internet library at: www.ibm.com/servers/eserver/zseries/zos/bkserv/

One exception is command syntax that is published in railroad track format; screen-readable copies of z/OS books with that syntax information are separately available in HTML zipped file form upon request to mhvrdfs@us.ibm.com.
Notices

This information was developed for products and services offered in the U.S.A.

IBM may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user’s responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not give you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation

Calls

- **Dynamic call**
  - See CALL statement
  - See also fetch

- **C++ calling C++ under CICS** 446
  - Calls between COBOL and VS COBOL II, under CICS 446
  - External references resolved at run time when made 14

- **Static call**
  - External references resolved at run time when made 14
  - In CICS COBOL applications 446

**Cataloged procedures**

- 103, 115
  - AFH WL (link-edit a Fortran program) 106
  - AFH W LG (link-edit and run a Fortran program) 106
  - AFH W N (change external names in conflict between C and Fortran) 107
  - AFH W R L (separate and link-edit Fortran object module) 107, 141
  - AFH W R LG (separate, link-edit and run object module) 107, 141
  - AHX F STA (Fortran reentrancy program) 141
  - CB CC (compile a C++ program) 105
  - CB CL (compile, prelink, and link-edit a C++ program) 105
  - CB CL LG (compile, prelink, link-edit, and run a C++ program) 105
  - CB CG (run a C++ program) 106
  - CB CL (prelink and link-edit a C++ program) 105
  - CB CL LG (prelink, link-edit, and run a C++ program) 106
  - CEE W G (load and run an HLL program) 107, 108
  - CEE WL (link-edit an HLL program) 108
  - CEE W LG (link-edit and run an HLL program) 109
  - CXX FILTER (invoke the demangle mangled names utility) 106

**Data set names**

- 104

**Cataloged procedures**

- 105
  - EDCC (compile a C program) 105
  - ED CL (compile and link-edit a C program)
    - Comparison with other cataloged procedures 105
    - Using with system programming facilities 610
  - ED CL LG (compile, link-edit, and run a C program) 105
cataloged procedure (continued)
EDCCLIB (compile and maintain an object library) 106
EDCCPLG (compile, prelink, link-edit, and run a C program) 105
EDCDLLRN (invoke the DLL rename utility) 106
EDCDSECT (invoke the DSECT conversion utility) 106
EDCLDEF (invoke locale object utility) 106
EDCLIB (invoke object library utility) 106
EDCPL (prelink and link-edit a C program) 105
IBM-supplied
EDCLIB 603
IEL1C (compile a PL/I program) 107
IEL1CG (compile, load, and run a PL/I program) 107
IEL1CL (compile and link-edit a PL/I program) 107
IEL1CLG (compile, link-edit, and run a PL/I program) 107
IGYWCG (compile, load, and run a COBOL program) 105
IGYWCL (compile and link-edit a COBOL program) 105
IGYWCLG (compile, link-edit, and run a COBOL program) 105
IGYWPL (prelink and link-edit a COBOL program) 107

    with CEE3CTY and CEEFMDT 380, 386
    with CESEECS callable service 353, 358
    with CESEECS, CESEEICI, and CEEISEC 359
  CEEDAYS — convert date to Lilian format
    with CEDATE and CEEDYWK 368
  CEEDCOD — decompose a condition token
    with CEEMOUT, CEENCOD, CEEMGET, and
      CEEMSG 273
  CEEDYWK — calculate day of week from Lilian date
    with CEDATE and CEEDAYS 368
  CEEFMDT — get default date and time format
    with CEE3CTY and CEDATM 380, 386
  CEEFMON — format monetary string 390, 392
  CEETFDS — format date and time into character
    string 393, 396
  CEEHDLR — register user-written condition handler
    calling from assembler 277, 283
    with CEE3SPM, CEE3GRN, and CEEMOUT 273
    with CEEGTST, CEECZST and CEEMCR 255, 264
    with CEESGL, CEEGQDT, and CEEMCR 269
  CEEISEC — convert integers to seconds
    with CESEECS, CESEEICI, and CEDATM 359
  CEELCNV — query locale numeric conventions
    with CEESETL 397, 401
  CEEMGET — get a message
    with CEEMOUT, CEENCOD, CEEDCOD, and
      CEEMSG 273
  CEEMOUT — dispatch a message
    with CEEHDLR, CEE3SPM, and CEE3GRN 273
    with CEENCOD, CEEMGET, CEEDCOD, and
      CEEMSG 273
examples (continued)

CEEMSG — get, format, and dispatch a message with CEEMOUT, CEENCOD, CEEMGET, and CEEDCOD 273
CEENCOD — construct a condition token with CEEMOUT, CEEMGET, CEEDCOD, and CEEMS 273
CEEQCN — query century window 343
CEEQDTC — query locale, date, and time conventions with CEESRTL 402, 406
CEEQRYL — query active locale environment with CEESRTL 410, 412
with CEESTXF 413, 416
CEESCN — set century window 343
CEESCOL — compare string collation weight 407, 410
CEESCI — convert seconds to integers with CEESCS, CEEISEC, and CEEDATM 359
CEESEC — convert timestamp to number of seconds multiple calls to 347, 352
using CEEDATM with 353, 358
with CEESCI, CEEISEC, and CEEDATM 359
CEESRTL — set locale operating environment with CEELCNV 397, 401
with CEEQDTC 402, 406
CEESMOD — perform modular arithmetic 427
CEEESLOG — calculate logarithm base e 429
CEESTXF — transform string into collation weights with CEEQRYL 413, 416

TCB
  driven 458
    initialization of first enclave 458
    termination of first enclave 458
  nested enclaves and 458
termination 204
  causes under Language Environment 148
  CEETERM macro and 487
  enclave
    as indicated in CEEAU_EQ_ABND field of
      CEEAE_FLAGS 465
    as indicated in CEEAU_EQ_ABTERM field of
      CEEAE_FLAGS 465
  CEEBXITA behavior during 461
  CEEBXITA function codes for 464
  terminating enclave created by an assembler
    routine 478
  terminating enclave created by CEESRT HLL
    user exit 471
preinitialized routines and 516
process
  CEEBXITA behavior during 462
  CEEBXITA function code for 464
  terminating process created by assembler
    routine 478
TERMTHDACT run-time option and 204
  thread 203
termination imminent step
  discussion of 202, 205
TERMTHDACT run-time option
  condition message and 202
  POSIX run-time option and 236
  termination imminent step and 204
TEST run-time option
  condition handling model and 205
  maximum allowable length in CEEXOPT macro 126
thread
  IMS and 452
  role in Language Environment program management
    model 163
  stack storage and 169
TIME command
  Language Environment date/time services and 510
  table of equivalent Language Environment
    services 510
Time Sharing Option (TSO)
  See TSO (Time Sharing Option)
token, condition
  See condition token
translator (CICS) 434, 443
TRAP run-time option
  ABPERC run-time option and 199
  CEEBXITA assembler user exit and 445
    abends that occur in CEEBXITA and 462
    using with CEEAU_EQ_AB_CODES to percolate
      a list of abend codes 462
  CICS condition handling and 443
  errors occurring in CEEBXITA and 462
  how CEEAU_EQ_ABND is affected by 465
  nested enclaves and
    enclaves created by C system() 561
    enclaves created by EXEC CICS LINK or EXEC
      CICS XCTL 557
    enclaves with a C or assembler main, created by
      SVC LINK 558, 559
    enclaves with a COBOL main, created by SVC
      LINK 559
    enclaves with a PL/I fetchable main 561, 562
TSO (Time Sharing Option)
  running for
    ALLOCATE command and 87, 89
    CALL command and 87, 88
    LOADGO command and 88, 89
    specifying run-time options for 87, 88, 89, 119
U
  user
    exit
      assembler 463
      for initialization 461, 520
      for termination 461, 462, 520
      HLL 470
      system exits in C Systems Programming
        Environment 613
      under CICS 464, 465
      under SORT/MERGE 618
    heap (initial heap)
      heap storage model and 174
    return code
      See also return code
      C language constructs that generate 152
      COBOL language constructs that generate 152
      Fortran language constructs that generate 153
      PL/I language constructs that generate 153
user comments 607
user-server environment 613
user-written condition handler
  allowing nested conditions in 241
  as opposed to condition manager 205
  C raise() function and 214, 215
  C signal() function and
    terminology differences between C and Language
      Environment 215
  CEESGL callable service and 198
  coding 237, 240
  examples 243, 283
EXEC CICS commands that cannot be used with 443
in ILC applications 241
in nested condition handling 241
in SORT/MERGE condition handling 618
registering with CEEHDLR 206
role in Language Environment condition management model 205
syntax for 238
TRAP run-time option and 198
USRHDLR run-time option and 240
USRHDLR run-time option description 240

V
variables 44
exported 44
vector instruction exceptions 226
VisualAge PL/I
z/OS UNIX support same as for C++ 93

W
WAIT command 510
warning error message (severity 1) 321
working storage 162
writable static
handled by prelinker 570
writable static map 573
WRITE command 510
WTO command
CEEMOUT callable service and 510
table of equivalent Language Environment services 510

X
XCTL command 510
XITPTR 463
XPLINK (Extra Performance Linkage) 29
CEEXR catalogued procedure 109
definition 29
downward-growing stack 31
glue code 31
guard page 31
how to enable 37
libraries 8
SCEEBIND 8
SCEELIB 9
non-XPLINK application 31
parameter conventions 36
register conventions 35
run-time option 37
stack overflow 34
when it should be used 36
when it should not be used 36
XPLINK application 31
XPLINK environment 31
XPLINK stack 31

XPLINK (Extra Performance Linkage) (continued)
XPLINK stack frame layout 32
XUFLOW run-time option
using to manipulate the PSW 199

Z
z/OS UNIX 150, 151, 175
24-bit AMODE programs, restriction on using 95
c89 utility
-c option 94
-o option 94
using 94
environments supported 93
environments, application program
shells through MVS batch 95
TSO/E 95
link-editing
C applications 93
Fortran applications 93
linking and running, basic 93
MVS application program load module
placing in file system 95
shells through MVS batch 95
parent and child processes 150
PL/I MTF application support 100
PL/I support in a non-IPT environment 99
position in Language Environment environment 4
POSIX default signal action 151
POSIX process termination mapping 151
prelinking under 93
process termination 150
running
applications under Language Environment 3
C application program for MVS batch 96
C applications 94
Fortran applications 93
from the z/OS UNIX shells 95
PL/I applications in a non-IPT environment 99
PL/I MTF applications 100
using BPXBATCH program 96
services 93
storage considerations 175
TERMTHDACT application 146
using Language Environment services 3
